What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. Amazon EC2 enables you to scale up or down to handle changes in requirements or spikes in popularity, reducing your need to forecast traffic.

For more information about cloud computing, see [What is cloud computing?](#)

Features of Amazon EC2

Amazon EC2 provides the following features:

- Virtual computing environments, known as *instances*
- Preconfigured templates for your instances, known as *Amazon Machine Images (AMIs)*, that package the bits you need for your server (including the operating system and additional software)
- Various configurations of CPU, memory, storage, and networking capacity for your instances, known as *instance types*
- Secure login information for your instances using *key pairs* (AWS stores the public key, and you store the private key in a secure place)
- Storage volumes for temporary data that's deleted when you stop, hibernate, or terminate your instance, known as *instance store volumes*
- Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS), known as *Amazon EBS volumes*
- Multiple physical locations for your resources, such as instances and Amazon EBS volumes, known as *Regions and Availability Zones*
- A firewall that enables you to specify the protocols, ports, and source IP ranges that can reach your instances using *security groups*
- Static IPv4 addresses for dynamic cloud computing, known as *Elastic IP addresses*
- Metadata, known as *tags*, that you can create and assign to your Amazon EC2 resources
- Virtual networks you can create that are logically isolated from the rest of the AWS Cloud, and that you can optionally connect to your own network, known as *virtual private clouds (VPCs)*

For more information about the features of Amazon EC2, see the [Amazon EC2 product page](#).

For more information about running your website on AWS, see [Web Hosting](#).

How to get started with Amazon EC2

First, you need to get set up to use Amazon EC2. After you are set up, you are ready to complete the Get Started tutorial for Amazon EC2. Whenever you need more information about an Amazon EC2 feature, you can read the technical documentation.

If you have questions about whether AWS is right for you, [contact AWS Sales](#). If you have technical questions about Amazon EC2, use the [Amazon EC2 forum](#).

Related services

You can provision Amazon EC2 resources, such as instances and volumes, directly using Amazon EC2. You can also provision Amazon EC2 resources using other services in AWS. For more information, see the following documentation:

- [Amazon EC2 Auto Scaling User Guide](#)
- [AWS CloudFormation User Guide](#)
- [AWS Elastic Beanstalk Developer Guide](#)
- [AWS OpsWorks User Guide](#)

To automatically distribute incoming application traffic across multiple instances, use Elastic Load Balancing. For more information, see the [Elastic Load Balancing User Guide](#).

To get a managed relational database in the cloud, use Amazon Relational Database Service (Amazon RDS) to launch a database instance. Although you can set up a database on an EC2 instance, Amazon

RDS offers the advantage of handling your database management tasks, such as patching the software, backing up, and storing the backups. For more information, see the [Amazon Relational Database Service Developer Guide](#).

To make it easier to manage Docker containers on a cluster of EC2 instances, use Amazon Elastic Container Service (Amazon ECS). For more information, see the [Amazon Elastic Container Service Developer Guide](#) or the [Amazon Elastic Container Service User Guide for AWS Fargate](#).

To monitor basic statistics for your instances and Amazon EBS volumes, use Amazon CloudWatch. For more information, see the [Amazon CloudWatch User Guide](#).

To detect potentially unauthorized or malicious use of your EC2 instances, use Amazon GuardDuty. For more information see the [Amazon GuardDuty User Guide](#).

Access Amazon EC2

Amazon EC2 provides a web-based user interface, the Amazon EC2 console. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting **EC2** from the console home page.

If you prefer to use a command line interface, you have the following options:

AWS Command Line Interface (CLI)

Provides commands for a broad set of AWS products, and is supported on Windows, Mac, and Linux. To get started, see [AWS Command Line Interface User Guide](#). For more information about the commands for Amazon EC2, see `ec2` in the [AWS CLI Command Reference](#).

AWS Tools for Windows PowerShell

Provides commands for a broad set of AWS products for those who script in the PowerShell environment. To get started, see the [AWS Tools for Windows PowerShell User Guide](#). For more information about the cmdlets for Amazon EC2, see the [AWS Tools for PowerShell Cmdlet Reference](#).

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about the resource types and properties for Amazon EC2, see [EC2 resource type reference](#) in the [AWS CloudFormation User Guide](#).

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named `Action`. For more information about the API actions for Amazon EC2, see [Actions](#) in the [Amazon EC2 API Reference](#).

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it easier for you to get started. For more information, see [Tools to Build on AWS](#).

Pricing for Amazon EC2

When you sign up for AWS, you can get started with Amazon EC2 for free using the [AWS Free Tier](#).

Amazon EC2 provides the following purchasing options for instances:

On-Demand Instances

Pay for the instances that you use by the second, with no long-term commitments or upfront payments.

Savings Plans

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

Reserved Instances

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

Spot Instances

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

For a complete list of charges and prices for Amazon EC2, see [Amazon EC2 pricing](#).

When calculating the cost of a provisioned environment, remember to include incidental costs such as snapshot storage for EBS volumes. To calculate the cost of a sample provisioned environment, see [Cloud Economics Center](#).

To see your bill, go to the **Billing and Cost Management Dashboard** in the [AWS Billing and Cost Management console](#). Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see [AWS Billing and Cost Management User Guide](#).

For an overview of Trusted Advisor, a service that helps you optimize the costs, security, and performance of your AWS environment, see [AWS Trusted Advisor](#).

PCI DSS compliance

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see [PCI DSS Level 1](#).

Set up to use Amazon EC2

Complete the tasks in this section to get set up for launching an Amazon EC2 instance for the first time:

1. [Sign up for AWS \(p. 5\)](#)
2. [Create a key pair \(p. 5\)](#)
3. [Create a security group \(p. 6\)](#)

When you are finished, you will be ready for the [Amazon EC2 Getting started \(p. 9\)](#) tutorial.

Sign up for AWS

When you sign up for Amazon Web Services, your AWS account is automatically signed up for all services in AWS , including Amazon EC2. You are charged only for the services that you use.

With Amazon EC2, you pay only for what you use. If you are a new AWS customer, you can get started with Amazon EC2 for free. For more information, see [AWS Free Tier](#).

If you have an AWS account already, skip to the next task. If you don't have an AWS account, use the following procedure to create one.

To create an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Create a key pair

AWS uses public-key cryptography to secure the login information for your instance. A Linux instance has no password; you use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your instance, then provide the private key when you log in using SSH.

If you haven't created a key pair already, you can create one by using the Amazon EC2 console. Note that if you plan to launch instances in multiple Regions, you'll need to create a key pair in each Region. For more information about Regions, see [Regions and Zones \(p. 1022\)](#).

To create your key pair

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Create key pair**.

4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
 5. For **Key pair type**, choose either **RSA** or **ED25519**. Note that **ED25519** keys are not supported for Windows instances.
 6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.
- If you chose **ED25519** in the previous step, the **Private key file format** options do not appear, and the private key format defaults to **pem**.
7. Choose **Create key pair**.
 8. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is determined by the file format you chose. Save the private key file in a safe place.
- Important**
This is the only chance for you to save the private key file.
9. If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 my-key-pair.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see [Error: Unprotected private key file \(p. 1719\)](#).

For more information, see [Amazon EC2 key pairs and Linux instances \(p. 1310\)](#).

Create a security group

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere.

Note that if you plan to launch instances in multiple Regions, you'll need to create a security group in each Region. For more information about Regions, see [Regions and Zones \(p. 1022\)](#).

Prerequisites

You'll need the public IPv4 address of your local computer. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address for you. Alternatively, you can use the search phrase "what is my IP address" in an Internet browser, or use the following service: [Check IP](#). If you are connecting through an Internet service provider (ISP) or from behind a firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

You can create a custom security group using one of the following methods.

New console

To create a security group with least privilege

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the top navigation bar, select a Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your key pair.

3. In the left navigation pane, choose **Security Groups**.
4. Choose **Create security group**.
5. For **Basic details**, do the following:
 - a. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `me_SG_uswest2`.
 - b. In the **VPC** list, select your default VPC for the Region.
6. For **Inbound rules**, create rules that allow specific traffic to reach your instance. For example, use the following rules for a web server that accepts HTTP and HTTPS traffic. For more examples, see [Security group rules for different use cases \(p. 1340\)](#).
 - a. Choose **Add rule**. For **Type**, choose **HTTP**. For **Source**, choose **Anywhere**.
 - b. Choose **Add rule**. For **Type**, choose **HTTPS**. For **Source**, choose **Anywhere**.
 - c. Choose **Add rule**. For **Type**, choose **SSH**. For **Source**, do one of the following:
 - Choose **My IP** to automatically add the public IPv4 address of your local computer.
 - Choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix `/32`, for example, `203.0.113.25/32`. If your company or your router allocates addresses from a range, specify the entire range, such as `203.0.113.0/24`.

Warning

For security reasons, do not choose **Anywhere** for **Source** with a rule for SSH. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. For **Outbound rules**, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

Old console

To create a security group with least privilege

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Choose **Create Security Group**.
4. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `me_SG_uswest2`.
5. In the **VPC** list, select your default VPC for the Region.
6. On the **Inbound rules** tab, create the following rules (choose **Add rule** for each new rule):
 - Choose **HTTP** from the **Type** list, and make sure that **Source** is set to **Anywhere** (`0.0.0.0/0`).
 - Choose **HTTPS** from the **Type** list, and make sure that **Source** is set to **Anywhere** (`0.0.0.0/0`).
 - Choose **SSH** from the **Type** list. In the **Source** box, choose **My IP** to automatically populate the field with the public IPv4 address of your local computer. Alternatively, choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix `/32`, for example, `203.0.113.25/32`. If your company allocates addresses from a range, specify the entire range, such as `203.0.113.0/24`.

Warning

For security reasons, do not allow SSH access from all IP addresses to your instance. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. On the **Outbound rules** tab, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

Command line

To create a security group with least privilege

Use one of the following commands:

- [create-security-group](#) (AWS CLI)
- [New-EC2SecurityGroup](#) (AWS Tools for Windows PowerShell)

For more information, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).

Tutorial: Get started with Amazon EC2 Linux instances

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You'll learn how to launch, connect to, and use a Linux instance. An *instance* is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

When you sign up for AWS, you can get started with Amazon EC2 using the [AWS Free Tier](#). If you created your AWS account less than 12 months ago, and have not already exceeded the free tier benefits for Amazon EC2, it will not cost you anything to complete this tutorial, because we help you select options that are within the free tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle.

Related tutorials

- If you'd prefer to launch a Windows instance, see this tutorial in the [Amazon EC2 User Guide for Windows Instances: Get started with Amazon EC2 Windows instances](#).
- If you'd prefer to use the command line, see this tutorial in the [AWS Command Line Interface User Guide: Using Amazon EC2 through the AWS CLI](#).

Overview

The instance is an Amazon EBS-backed instance (meaning that the root volume is an EBS volume). You can either specify the Availability Zone in which your instance runs, or let Amazon EC2 select an Availability Zone for you. You can think of an Availability Zone as an isolated data center.

When you launch your instance, you secure it by specifying a key pair (to prove your identity) and a security group (which acts as a virtual firewall to control ingoing and outgoing traffic). When you connect to your instance, you must specify the private key of the key pair that you specified when launching your instance.

Prerequisites

Before you begin, be sure that you've completed the steps in [Set up to use Amazon EC2 \(p. 5\)](#).

Step 1: Launch an instance

You can launch a Linux instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you launch your first instance quickly, so it doesn't cover all possible options. For more information about the advanced options, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#). For information about other ways to launch your instance, see [Launch your instance \(p. 578\)](#).

To launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console dashboard, choose **Launch Instance**.
3. The **Choose an Amazon Machine Image (AMI)** page displays a list of basic configurations, called *Amazon Machine Images (AMIs)*, that serve as templates for your instance. Select an HVM version of Amazon Linux 2. Notice that these AMIs are marked "Free tier eligible."
4. On the **Choose an Instance Type** page, you can select the hardware configuration of your instance. Select the `t2.micro` instance type, which is selected by default. The `t2.micro` instance type is eligible for the free tier. In Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the free tier. For more information, see [AWS Free Tier](#).
5. On the **Choose an Instance Type** page, choose **Review and Launch** to let the wizard complete the other configuration settings for you.
6. On the **Review Instance Launch** page, under **Security Groups**, you'll see that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select the security group that you created when getting set up using the following steps:
 - a. Choose **Edit security groups**.
 - b. On the **Configure Security Group** page, ensure that **Select an existing security group** is selected.

- c. Select your security group from the list of existing security groups, and then choose **Review and Launch**.
7. On the **Review Instance Launch** page, choose **Launch**.
8. When prompted for a key pair, select **Choose an existing key pair**, then select the key pair that you created when getting set up.

Warning

Don't select **Proceed without a key pair**. If you launch your instance without a key pair, then you can't connect to it.

When you are ready, select the acknowledgement check box, and then choose **Launch Instances**.

9. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.
10. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch. When you launch an instance, its initial state is **pending**. After the instance starts, its state changes to **running** and it receives a public DNS name. (If the **Public IPv4 DNS** column is hidden, choose the settings icon () in the top-right corner, toggle on **Public IPv4 DNS**, and choose **Confirm**.)
11. It can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks; you can view this information in the **Status check** column.

Step 2: Connect to your instance

There are several ways to connect to your Linux instance. For more information, see [Connect to your Linux instance \(p. 611\)](#).

Important

You can't connect to your instance unless you launched it with a key pair for which you have the **.pem** file and you launched it with a security group that allows SSH access from your computer. If you can't connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#) for assistance.

Step 3: Clean up your instance

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see [Next steps \(p. 12\)](#).

Important

Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.

If you launched an instance that is not within the [AWS Free Tier](#), you'll stop incurring charges for that instance as soon as the instance status changes to **shutting down** or **terminated**. To keep your instance for later, but not incur charges, you can stop the instance now and then start it again later. For more information, see [Stop and start your instance \(p. 637\)](#).

To terminate your instance

1. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
2. Choose **Instance state, Terminate instance**.
3. Choose **Terminate** when prompted for confirmation.

Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console for a short while, and then the entry is automatically deleted. You cannot remove the terminated instance from the console display yourself.

Next steps

After you start your instance, you might want to try some of the following exercises:

- Learn how to remotely manage your EC2 instance using Run Command. For more information, see [AWS Systems Manager Run Command](#) in the *AWS Systems Manager User Guide*.
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier. For more information, see [Tracking your AWS Free Tier usage](#) in the *AWS Billing and Cost Management User Guide*.
- Add an EBS volume. For more information, see [Create an Amazon EBS volume \(p. 1371\)](#) and [Attach an Amazon EBS volume to an instance \(p. 1375\)](#).
- Install the LAMP stack. For more information, see [Tutorial: Install a LAMP web server on Amazon Linux 2 \(p. 25\)](#).

Best practices for Amazon EC2

This list of practices will help you get the maximum benefit from Amazon EC2.

Security

- Manage access to AWS resources and APIs using identity federation, IAM users, and IAM roles. Establish credential management policies and procedures for creating, distributing, rotating, and revoking AWS access credentials. For more information, see [IAM Best Practices](#) in the *IAM User Guide*.
- Implement the least permissive rules for your security group. For more information, see [Security group rules \(p. 1326\)](#).
- Regularly patch, update, and secure the operating system and applications on your instance. For more information about updating Amazon Linux 2 or the Amazon Linux AMI, see [Manage software on your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

Storage

- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see [Storage for the root device \(p. 106\)](#).
- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.
- Encrypt EBS volumes and snapshots. For more information, see [Amazon EBS encryption \(p. 1542\)](#).

Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see [Instance metadata and user data \(p. 726\)](#) and [Tag your Amazon EC2 resources \(p. 1692\)](#).
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you'll need them. For more information, see [Amazon EC2 service quotas \(p. 1706\)](#).

Backup and recovery

- Regularly back up your EBS volumes using [Amazon EBS snapshots \(p. 1403\)](#), and create an [Amazon Machine Image \(AMI\) \(p. 103\)](#) from your instance to save the configuration as a template for launching future instances.
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see [Amazon EC2 instance IP addressing \(p. 1037\)](#).
- Monitor and respond to events. For more information, see [Monitor Amazon EC2 \(p. 942\)](#).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see [Elastic network interfaces \(p. 1091\)](#). For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

- Regularly test the process of recovering your instances and Amazon EBS volumes if they fail.

Networking

- Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.

Tutorials for Amazon EC2 Instances Running Linux

The following tutorials show you how to perform common tasks using EC2 instances running Linux. AWS provides Amazon Linux 2022, Amazon Linux 2, and the Amazon Linux AMI. For more information, see [Amazon Linux 2](https://aws.amazon.com/amazon-linux-2022/), <https://aws.amazon.com/amazon-linux-2022/>, and [Amazon Linux AMI](#). Tutorial: Install a LAMP web server on Amazon Linux 2022

The following procedures help you install an Apache web server with PHP and [MariaDB](#) (a community-developed fork of MySQL) support on your Amazon Linux 2022 instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important

If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux AMI, see [Tutorial: Install a LAMP web server on the Amazon Linux AMI \(p. 35\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [AWS Docs - Install ALAMP Server - AL2](#) Automation document.

Tasks

- [Step 1: Prepare the LAMP server \(p. 16\)](#)
- [Step 2: Test your LAMP server \(p. 19\)](#)
- [Step 3: Secure the database server \(p. 20\)](#)
- [Step 4: \(Optional\) Install phpMyAdmin \(p. 21\)](#)

- [Troubleshoot \(p. 24\)](#)
- [Related topics \(p. 24\)](#)

Step 1: Prepare the LAMP server

Prerequisites

- This tutorial assumes that you have already launched a new instance using Amazon Linux 2022, with a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance \(p. 10\)](#). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).
- The following procedure installs the latest PHP version available on Amazon Linux 2022, currently 7.4;. If you plan to use PHP applications other than those described in this tutorial, you should check their compatibility with 7.4.

To prepare the LAMP server

1. [Connect to your instance \(p. 11\)](#).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Install the latest versions of Apache web server, and PHP packages for Amazon Linux 2022.

```
[ec2-user ~]$ sudo yum install -y httpd wget php-fpm php-mysqli php-json php php-devel
```

To set up a LAMP web server on Amazon Linux 2, see [Tutorial: Install a LAMP web server on Amazon Linux 2 \(p. 25\)](#).

4. Install the MariaDB, software packages. Use the `dnf install` command to install multiple software packages and all related dependencies at the same time.

```
[ec2-user ~]$ sudo dnf install mariadb105-server
```

You can view the current versions of these packages using the following command:

```
yum info package_name
```

5. Start the Apache web server.

```
[ec2-user ~]$ sudo systemctl start httpd
```

6. Use the `systemctl` command to configure the Apache web server to start at each system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd
```

You can verify that `httpd` is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

7. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a **launch-wizard-*N*** security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. Choose **Instances** and select your instance.
 - c. On the **Security** tab, view the inbound rules. You should see the following rule:

Port range	Protocol	Source
22	tcp	0.0.0.0/0

Warning

Using 0.0.0.0/0 allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

- d. Choose the link for the security group. Using the procedures in [Add rules to a security group \(p. 1333\)](#), add a new inbound security rule with the following values:
 - **Type:** HTTP
 - **Protocol:** TCP
 - **Port Range:** 80
 - **Source:** Custom
8. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. If there is no content in /var/www/html, you should see the Apache test page. You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, choose **Show/Hide Columns** (the gear-shaped icon) and choose **Public DNS**).

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

Important

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Test Page

This page is used to test the proper operation of the Apache HTTP server after it has been installed. If you can read this page, it means that the Apache HTTP server installed at this site is working properly.

If you are a member of the general public:

The fact that you are seeing this page indicates that the website you just visited is either experiencing problems, or is undergoing routine maintenance.

If you would like to let the administrators of this website know that you've seen this page instead of the page you expected, you should send them e-mail. In general, mail sent to the name "webmaster" and directed to the website's domain should reach the appropriate person.

For example, if you experienced problems while visiting www.example.com, you should send e-mail to "webmaster@example.com".

If you are the website administrator:

You may now add content to the directory `/var/www/html/`. Note that until you do so, people visiting your website will see this page, and not your content. To prevent this page from ever being used, follow the instructions in the file `/etc/httpd/conf.d/welcome.conf`.

You are free to use the image below on web sites powered by the Apache HTTP Server:

2.4

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.

To allow the `ec2-user` account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions

1. Add your user (in this case, `ec2-user`) to the `apache` group.

```
[ec2-user ~]$ sudo usermod -a -G apache ec2-user
```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
 - a. Log out (use the `exit` command or close the terminal window):

```
[ec2-user ~]$ exit
```

- b. To verify your membership in the `apache` group, reconnect to your instance, and then run the following command:

```
[ec2-user ~]$ groups
ec2-user adm wheel apache systemd-journal
```

3. Change the group ownership of `/var/www` and its contents to the `apache` group.

```
[ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of `/var/www` and its subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www && find /var/www -type d -exec sudo chmod 2775 {} \;
```

5. To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

To secure your web server (Optional)

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

Step 2: Test your LAMP server

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.

To test your LAMP server

1. Create a PHP file in the Apache document root.

```
[ec2-user ~]$ echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in [To set file permissions \(p. 18\)](#).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page:

If you do not see this page, verify that the `/var/www/html/phpinfo.php` file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command.

```
[ec2-user ~]$ sudo yum list installed httpd mariadb-server php-mysqlnd
```

If any of the required packages are not listed in your output, install them with the **sudo yum install package** command. Also verify that the `php7.2` and `lamp-mariadb10.2-php7.2` extras are enabled in the output of the `amazon-linux-extras` command.

3. Delete the `phpinfo.php` file. Although this can be useful information, it should not be broadcast to the internet for security reasons.

```
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at `/var/www/html`, you should be able to view that content at the public DNS address for your instance.

Step 3: Secure the database server

The default installation of the MariaDB server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MariaDB server, we recommend performing this procedure.

To secure the MariaDB server

1. Start the MariaDB server.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

2. Run `mysql_secure_installation`.

```
[ec2-user ~]$ sudo mysql_secure_installation
```

- a. When prompted, type a password for the root account.
 - i. Type the current root password. By default, the root account does not have a password set. Press Enter.
 - ii. Type **y** to set a password, and type a secure password twice. For more information about creating a secure password, see <https://identitysafe.norton.com/password-generator/>. Make sure to store this password in a safe place.
 - Setting a root password for MariaDB is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.
 - b. Type **y** to remove the anonymous user accounts.
 - c. Type **y** to disable the remote root login.
 - d. Type **y** to remove the test database.
 - e. Type **y** to reload the privilege tables and save your changes.
3. (Optional) If you do not plan to use the MariaDB server right away, stop it. You can restart it when you need it again.

```
[ec2-user ~]$ sudo systemctl stop mariadb
```

4. (Optional) If you want the MariaDB server to start at every boot, type the following command.

```
[ec2-user ~]$ sudo systemctl enable mariadb
```

Step 4: (Optional) Install phpMyAdmin

phpMyAdmin is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

Important

We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see [Securing your phpMyAdmin installation](#). For general information about securing a web server on an EC2 instance, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

To install phpMyAdmin

1. Install the required dependencies.

```
[ec2-user ~]$ sudo yum install php-mbstring php-xml -y
```

2. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

3. Restart php-fpm.

```
[ec2-user ~]$ sudo systemctl restart php-fpm
```

4. Navigate to the Apache document root at /var/www/html.

```
[ec2-user ~]$ cd /var/www/html
```

5. Select a source package for the latest phpMyAdmin release from <https://www.phpmyadmin.net/downloads>. To download the file directly to your instance, copy the link and paste it into a **wget** command, as in this example:

```
[ec2-user html]$ wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it with the following command.

```
[ec2-user html]$ mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz -C phpMyAdmin --strip-components 1
```

7. Delete the *phpMyAdmin-latest-all-languages.tar.gz* tarball.

```
[ec2-user html]$ rm phpMyAdmin-latest-all-languages.tar.gz
```

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:

10. Log in to your phpMyAdmin installation with the `root` user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. We suggest that you begin by manually creating the configuration file, as follows:

- a. To start with a minimal configuration file, use your favorite text editor to create a new file, and then copy the contents of `config.sample.inc.php` into it.

- b. Save the file as `config.inc.php` in the `phpMyAdmin` directory that contains `index.php`.
- c. Refer to post-file creation instructions in the [Using the Setup script](#) section of the `phpMyAdmin` installation instructions for any additional setup.

For information about using `phpMyAdmin`, see the [phpMyAdmin User Guide](#).

Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

You can verify that `httpd` is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the `httpd` process is not running, repeat the steps described in [To prepare the LAMP server \(p. 26\)](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

I can't connect to my server using HTTPS

Perform the following checks to see if your Apache web server is configured to support HTTPS.

- **Is the web server correctly configured?**

After you install Apache, the server is configured for HTTP traffic. To support HTTPS, enable TLS on the server and install an SSL certificate. For information, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTPS traffic on port 443. For more information, see [Add rules to a security group \(p. 1333\)](#).

Tutorial: Install a LAMP web server on Amazon Linux 2

The following procedures help you install an Apache web server with PHP and [MariaDB](#) (a community-developed fork of MySQL) support on your Amazon Linux 2 instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important

If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux AMI, see [Tutorial: Install a LAMP web server on the Amazon Linux AMI \(p. 35\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [AWS Docs - Install ALAMP Server - AL2](#) Automation document.

Tasks

- [Step 1: Prepare the LAMP server \(p. 25\)](#)
- [Step 2: Test your LAMP server \(p. 29\)](#)
- [Step 3: Secure the database server \(p. 30\)](#)
- [Step 4: \(Optional\) Install phpMyAdmin \(p. 31\)](#)
- [Troubleshoot \(p. 34\)](#)
- [Related topics \(p. 34\)](#)

Step 1: Prepare the LAMP server

Prerequisites

- This tutorial assumes that you have already launched a new instance using Amazon Linux 2, with a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance \(p. 10\)](#). You must also have configured your security group to allow SSH (port 22), HTTP (port

80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

- The following procedure installs the latest PHP version available on Amazon Linux 2, currently PHP 7.2. If you plan to use PHP applications other than those described in this tutorial, you should check their compatibility with PHP 7.2.

Note

Note, this install package is bundled with Mariadb (lamp-mariadb10.2-php7.2). A number of previous vulnerabilities in php7.2 have since been patched via [backports](#) by AWS, however your particular security software may still flag this version of PHP. Ensure you perform system updates frequently. You can choose to install a newer version of PHP, however you will need to install MariaDB separately.

To prepare the LAMP server

1. [Connect to your instance \(p. 11\)](#).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Install the `lamp-mariadb10.2-php7.2` and `php7.2` Amazon Linux Extras repositories to get the latest versions of the LAMP MariaDB and PHP packages for Amazon Linux 2.

```
[ec2-user ~]$ sudo amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
```

If you receive an error stating `sudo: amazon-linux-extras: command not found`, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

```
cat /etc/system-release
```

To set up a LAMP web server on Amazon Linux AMI , see [Tutorial: Install a LAMP web server on the Amazon Linux AMI \(p. 35\)](#).

4. Now that your instance is current, you can install the Apache web server, MariaDB, and PHP software packages.

Use the `yum install` command to install multiple software packages and all related dependencies at the same time.

```
[ec2-user ~]$ sudo yum install -y httpd mariadb-server
```

You can view the current versions of these packages using the following command:

```
yum info package_name
```

5. Start the Apache web server.

```
[ec2-user ~]$ sudo systemctl start httpd
```

6. Use the **systemctl** command to configure the Apache web server to start at each system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd
```

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

7. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a **launch-wizard-N** security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. Choose **Instances** and select your instance.
 - c. On the **Security** tab, view the inbound rules. You should see the following rule:

Port range	Protocol	Source
22	tcp	0.0.0.0/0

Warning

Using 0.0.0.0/0 allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

- d. Choose the link for the security group. Using the procedures in [Add rules to a security group \(p. 1333\)](#), add a new inbound security rule with the following values:
 - **Type:** HTTP
 - **Protocol:** TCP
 - **Port Range:** 80
 - **Source:** Custom
8. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. If there is no content in /var/www/html, you should see the Apache test page. You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, choose **Show/Hide Columns** (the gear-shaped icon) and choose **Public DNS**).

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

Important

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Test Page

This page is used to test the proper operation of the Apache HTTP server after it has been installed. If you can read this page, it means that the Apache HTTP server installed at this site is working properly.

If you are a member of the general public:

The fact that you are seeing this page indicates that the website you just visited is either experiencing problems, or is undergoing routine maintenance.

If you would like to let the administrators of this website know that you've seen this page instead of the page you expected, you should send them e-mail. In general, mail sent to the name "webmaster" and directed to the website's domain should reach the appropriate person.

For example, if you experienced problems while visiting www.example.com, you should send e-mail to "webmaster@example.com".

If you are the website administrator:

You may now add content to the directory `/var/www/html/`. Note that until you do so, people visiting your website will see this page, and not your content. To prevent this page from ever being used, follow the instructions in the file `/etc/httpd/conf.d/welcome.conf`.

You are free to use the image below on web sites powered by the Apache HTTP Server:

2.4

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.

To allow the `ec2-user` account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions

1. Add your user (in this case, `ec2-user`) to the `apache` group.

```
[ec2-user ~]$ sudo usermod -a -G apache ec2-user
```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
 - a. Log out (use the `exit` command or close the terminal window):

```
[ec2-user ~]$ exit
```

- b. To verify your membership in the `apache` group, reconnect to your instance, and then run the following command:

```
[ec2-user ~]$ groups
ec2-user adm wheel apache systemd-journal
```

3. Change the group ownership of `/var/www` and its contents to the `apache` group.

```
[ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of `/var/www` and its subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www && find /var/www -type d -exec sudo chmod 2775 {} \;
```

5. To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

To secure your web server (Optional)

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

Step 2: Test your LAMP server

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.

To test your LAMP server

1. Create a PHP file in the Apache document root.

```
[ec2-user ~]$ echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in [To set file permissions \(p. 28\)](#).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page:

[ec2-user ~]$ sudo systemctl stop mariadb
```

4. (Optional) If you want the MariaDB server to start at every boot, type the following command.

```

Step 4: (Optional) Install phpMyAdmin

phpMyAdmin is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

Important

We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see [Securing your phpMyAdmin installation](#). For general information about securing a web server on an EC2 instance, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

To install phpMyAdmin

1. Install the required dependencies.

```
[ec2-user ~]$ sudo yum install php-mbstring php-xml -y
```

2. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd

5. Select a source package for the latest phpMyAdmin release from <https://www.phpmyadmin.net/downloads>. To download the file directly to your instance, copy the link and paste it into a **wget** command, as in this example:

```
[ec2-user html]$ wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it with the following command.

```
[ec2-user html]$ mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz -C phpMyAdmin --strip-components 1

```

You should see the phpMyAdmin login page:

10. Log in to your phpMyAdmin installation with the `root` user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. We suggest that you begin by manually creating the configuration file, as follows:

- a. To start with a minimal configuration file, use your favorite text editor to create a new file, and then copy the contents of `config.sample.inc.php` into it.

Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

You can verify that `httpd` is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the `httpd` process is not running, repeat the steps described in [To prepare the LAMP server \(p. 26\)](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

I can't connect to my server using HTTPS

Perform the following checks to see if your Apache web server is configured to support HTTPS.

- **Is the web server correctly configured?**

After you install Apache, the server is configured for HTTP traffic. To support HTTPS, enable TLS on the server and install an SSL certificate. For information, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTPS traffic on port 443. For more information, see [Add rules to a security group \(p. 1333\)](#).

Tutorial: Install a LAMP web server on the Amazon Linux AMI

The following procedures help you install an Apache web server with PHP and MySQL support on your Amazon Linux instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important

If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux 2, see [Tutorial: Install a LAMP web server on Amazon Linux 2 \(p. 25\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [AWSdocs-InstallALAMPServer-AL](#) Automation document.

Tasks

- [Step 1: Prepare the LAMP server \(p. 35\)](#)
- [Step 2: Test your Lamp server \(p. 38\)](#)
- [Step 3: Secure the database server \(p. 39\)](#)
- [Step 4: \(Optional\) Install phpMyAdmin \(p. 40\)](#)
- [Troubleshoot \(p. 43\)](#)
- [Related topics \(p. 44\)](#)

Step 1: Prepare the LAMP server

Prerequisites

This tutorial assumes that you have already launched a new instance using the Amazon Linux AMI, with a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance \(p. 10\)](#). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

To install and start the LAMP web server with the Amazon Linux AMI

1. [Connect to your instance \(p. 11\)](#).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, you can install the Apache web server, MySQL, and PHP software packages.

Important

Some applications may not be compatible with the following recommended software environment. Before installing these packages, check whether your LAMP applications are compatible with them. If there is a problem, you may need to install an alternative environment. For more information, see [The application software I want to run on my server is incompatible with the installed PHP version or other software \(p. 43\)](#)

Use the `yum install` command to install multiple software packages and all related dependencies at the same time.

```
[ec2-user ~]$ sudo yum install -y httpd24 php72 mysql57-server php72-mysqlnd
```

If you receive the error `No package package-name available`, then your instance was not launched with the Amazon Linux AMI (perhaps you are using Amazon Linux 2 instead). You can view your version of Amazon Linux with the following command.

```
cat /etc/system-release
```

4. Start the Apache web server.

```
[ec2-user ~]$ sudo service httpd start
Starting httpd: [ OK ]
```

5. Use the `chkconfig` command to configure the Apache web server to start at each system boot.

```
[ec2-user ~]$ sudo chkconfig httpd on
```

The `chkconfig` command does not provide any confirmation message when you successfully use it to enable a service.

You can verify that `httpd` is on by running the following command:

```
[ec2-user ~]$ chkconfig --list httpd
httpd           0:off   1:off   2:on    3:on    4:on    5:on    6:off
```

Here, `httpd` is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

6. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a `launch-wizard-N` security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

- b. Choose **Instances** and select your instance.
- c. On the **Security** tab, view the inbound rules. You should see the following rule:

Port range	Protocol	Source
22	tcp	0.0.0.0/0

Warning

Using 0.0.0.0/0 allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

- d. Choose the link for the security group. Using the procedures in [Add rules to a security group \(p. 1333\)](#), add a new inbound security rule with the following values:
 - **Type:** HTTP
 - **Protocol:** TCP
 - **Port Range:** 80
 - **Source:** Custom
7. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. You can get the public DNS address for your instance using the Amazon EC2 console. If there is no content in /var/www/html, you should see the Apache test page. When you add content to the document root, your content appears at the public DNS address of your instance instead of the test page.

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is /var/www/html, which by default is owned by root.

```
[ec2-user ~]$ ls -l /var/www
total 16
drwxr-xr-x 2 root root 4096 Jul 12 01:00 cgi-bin
drwxr-xr-x 3 root root 4096 Aug 7 00:02 error
drwxr-xr-x 2 root root 4096 Jan 6 2012 html
drwxr-xr-x 3 root root 4096 Aug 7 00:02 icons
drwxr-xr-x 2 root root 4096 Aug 7 21:17 noindex
```

To allow the ec2-user account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

To set file permissions

1. Add your user (in this case, ec2-user) to the apache group.

```
[ec2-user ~]$ sudo usermod -a -G apache ec2-user
```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
 - a. Log out (use the **exit** command or close the terminal window):

```
[ec2-user ~]$ exit
```

- b. To verify your membership in the apache group, reconnect to your instance, and then run the following command:

```
[ec2-user ~]$ groups  
ec2-user wheel apache
```

3. Change the group ownership of /var/www and its contents to the apache group.

```
[ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of /var/www and its subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www  
[ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} \;
```

5. To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

(Optional) Secure your web server

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI \(p. 74\)](#).

Step 2: Test your Lamp server

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.

To test your LAMP web server

1. Create a PHP file in the Apache document root.

```
[ec2-user ~]$ echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in [Step 1: Prepare the LAMP server \(p. 35\)](#).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page:

If you do not see this page, verify that the `/var/www/html/phpinfo.php` file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command. The package versions in the second column do not need to match this example output.

```
[ec2-user ~]$ sudo yum list installed httpd24 php72 mysql57-server php72-mysqlind
Loaded plugins: priorities, update-motd, upgrade-helper
Installed Packages
httpd24.x86_64                  2.4.25-1.68.amzn1                               @amzn-

php70.x86_64                      7.0.14-1.20.amzn1                               @amzn-
updates
php70-mysqlind.x86_64              7.0.14-1.20.amzn1                               @amzn-
updates
```

If any of the required packages are not listed in your output, install them using the **`sudo yum install package`** command.

3. Delete the `phpinfo.php` file. Although this can be useful information, it should not be broadcast to the internet for security reasons.

```
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

Step 3: Secure the database server

The default installation of the MySQL server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MySQL server, we recommend performing this procedure.

To secure the database server

1. Start the MySQL server.

```
[ec2-user ~]$ sudo service mysqld start
Initializing MySQL database:
...
PLEASE REMEMBER TO SET A PASSWORD FOR THE MySQL root USER !
...
Starting mysqld: [ OK ]
```

2. Run **mysql_secure_installation**.

```
[ec2-user ~]$ sudo mysql_secure_installation
```

- a. When prompted, type a password for the root account.
 - i. Type the current root password. By default, the root account does not have a password set. Press Enter.
 - ii. Type **y** to set a password, and type a secure password twice. For more information about creating a secure password, see <https://identitysafe.norton.com/password-generator/>. Make sure to store this password in a safe place.
- Setting a root password for MySQL is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.
- b. Type **y** to remove the anonymous user accounts.
- c. Type **y** to disable the remote root login.
- d. Type **y** to remove the test database.
- e. Type **y** to reload the privilege tables and save your changes.
3. (Optional) If you do not plan to use the MySQL server right away, stop it. You can restart it when you need it again.

```
[ec2-user ~]$ sudo service mysqld stop
Stopping mysqld: [ OK ]
```

4. (Optional) If you want the MySQL server to start at every boot, type the following command.

```
[ec2-user ~]$ sudo chkconfig mysqld on
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at `/var/www/html`, you should be able to view that content at the public DNS address for your instance.

Step 4: (Optional) Install phpMyAdmin

To install phpMyAdmin

phpMyAdmin is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

Important

We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see [Securing your phpMyAdmin installation](#).

Note

The Amazon Linux package management system does not currently support the automatic installation of phpMyAdmin in a PHP 7 environment. This tutorial describes how to install phpMyAdmin manually.

1. Log in to your EC2 instance using SSH.
2. Install the required dependencies.

```
[ec2-user ~]$ sudo yum install php72-mbstring.x86_64 -y
```

3. Restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
Stopping httpd:                                     [    OK    ]
Starting httpd:                                     [    OK    ]
```

4. Navigate to the Apache document root at /var/www/html.

```
[ec2-user ~]$ cd /var/www/html
[ec2-user html]$
```

5. Select a source package for the latest phpMyAdmin release from <https://www.phpmyadmin.net/downloads>. To download the file directly to your instance, copy the link and paste it into a `wget` command, as in this example:

```
[ec2-user html]$ wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it using the following command.

```
[ec2-user html]$ mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz -C phpMyAdmin --strip-components 1
```

7. Delete the `phpMyAdmin-latest-all-languages.tar.gz` tarball.

```
[ec2-user html]$ rm phpMyAdmin-latest-all-languages.tar.gz
```

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]$ sudo service mysqld start
Starting mysqld:                                     [    OK    ]
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:

10. Log in to your phpMyAdmin installation with the `root` user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. To configure phpMyAdmin, you can [manually create a configuration file](#), [use the setup console](#), or combine both approaches.

For information about using phpMyAdmin, see the [phpMyAdmin User Guide](#).

Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser.

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ chkconfig --list httpd
httpd           0:off    1:off    2:on     3:on     4:on     5:on     6:off
```

Here, **httpd** is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

If the **httpd** process is not running, repeat the steps described in [Step 1: Prepare the LAMP server \(p. 35\)](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group \(p. 1333\)](#).

The application software I want to run on my server is incompatible with the installed PHP version or other software

This tutorial recommends installing the most up-to-date versions of Apache HTTP Server, PHP, and MySQL. Before installing an additional LAMP application, check its requirements to confirm that it is compatible with your installed environment. If the latest version of PHP is not supported, it is possible (and entirely safe) to downgrade to an earlier supported configuration. You can also install more than one version of PHP in parallel, which solves certain compatibility problems with a minimum of effort. For information about configuring a preference among multiple installed PHP versions, see [Amazon Linux AMI 2016.09 Release Notes](#).

How to downgrade

The well-tested previous version of this tutorial called for the following core LAMP packages:

- **httpd24**
- **php56**
- **mysql55-server**
- **php56-mysqlnd**

If you have already installed the latest packages as recommended at the start of this tutorial, you must first uninstall these packages and other dependencies as follows:

```
[ec2-user ~]$ sudo yum remove -y httpd24 php72 mysql57-server php72-mysqlnd perl-DBD-MySQL57
```

Next, install the replacement environment:

```
[ec2-user ~]$ sudo yum install -y httpd24 php56 mysql55-server php56-mysqlnd
```

If you decide later to upgrade to the recommended environment, you must first remove the customized packages and dependencies:

```
[ec2-user ~]$ sudo yum remove -y httpd24 php56 mysql55-server php56-mysqlnd perl-DBD-MySQL
```

Now you can install the latest packages, as described earlier.

Tutorial: Configure SSL/TLS on Amazon Linux 2022

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with Amazon Linux 2022 and Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from [AWS Certificate Manager](#) instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. Amazon Linux 2022 disables server-side support for all versions of SSL by default. [Security standards bodies](#) consider TLS 1.0 to be unsafe, and both TLS 1.0 and TLS 1.1 are on track to be formally [deprecated](#) by the IETF. This tutorial contains guidance based exclusively on enabling TLS 1.2. (A newer TLS 1.3 protocol exists, but it is not installed by default on Amazon Linux 2022.) For more information about the updated encryption standards, see [RFC 7568](#) and [RFC 8446](#).

This tutorial refers to modern web encryption simply as TLS.

Important

These procedures are intended for use with Amazon Linux 2022. We also assume that you are starting with a new Amazon EC2 instance. If you are trying to set up an EC2 instance running a different distribution, or an instance running an old version of Amazon Linux, some procedures in this tutorial might not work. For the Amazon Linux AMI, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI \(p. 74\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For Red Hat Enterprise Linux, see the following: [Setting up the Apache HTTP Web Server](#). For other distributions, see their specific documentation.

Note

Alternatively, you can use AWS Certificate Manager (ACM) for AWS Nitro enclaves, which is an enclave application that allows you to use public and private SSL/TLS certificates with your web applications and servers running on Amazon EC2 instances with AWS Nitro Enclaves. Nitro Enclaves is an Amazon EC2 capability that enables creation of isolated compute environments to protect and securely process highly sensitive data, such as SSL/TLS certificates and private keys. ACM for Nitro Enclaves works with `nginx` running on your Amazon EC2 Linux instance to create private keys, to distribute certificates and private keys, and to manage certificate renewals.

To use ACM for Nitro Enclaves, you must use an enclave-enabled Linux instance.

For more information, see [What is AWS Nitro Enclaves?](#) and [AWS Certificate Manager for Nitro Enclaves](#) in the [AWS Nitro Enclaves User Guide](#).

- [Troubleshoot \(p. 54\)](#)
- [Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2022 \(p. 55\)](#)

Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed Amazon Linux 2022 instance. For more information, see [Step 1: Launch an instance \(p. 10\)](#).
- Configure your security groups to allow your instance to accept connections on the following TCP ports:
 - SSH (port 22)
 - HTTP (port 80)
 - HTTPS (port 443)

For more information, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

- Install the Apache web server. For step-by-step instructions, see [Tutorial: Install a LAMP Web Server on Amazon Linux 2022 \(p. 25\)](#). Only the `httpd` package and its dependencies are needed, so you can ignore the instructions involving PHP and MariaDB.
- To identify and authenticate websites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public website, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use [Amazon Route 53](#).

Step 1: Enable TLS on the server

This procedure takes you through the process of setting up TLS on Amazon Linux 2022 with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site are greeted by security warnings.

To enable TLS on a server

1. [Connect to your instance \(p. 11\)](#) and confirm that Apache is running.

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the returned value is not "enabled," start Apache and set it to start each time the system boots.

```
[ec2-user ~]$ sudo systemctl start httpd && sudo systemctl enable httpd
```

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

Note

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo dnf install openssl mod_ssl
```

3. After you enter the following command, you will be taken to a prompt where you can enter information about your site.

```
[ec2-user ~]$ sudo openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout /etc/pki/tls/private/apache-selfsigned.key -out /etc/pki/tls/certs/apache-selfsigned.crt
```

This generates a new file `localhost.crt` in the `/etc/pki/tls/certs/` directory. The specified file name matches the default that is assigned in the `SSLCertificateFile` directive in `/etc/httpd/conf.d/ssl.conf`.

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

- `/etc/httpd/conf.d/ssl.conf`

The configuration file for `mod_ssl`. It contains *directives* telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept. This will be your local certificate file:

- `/etc/pki/tls/certs/localhost.crt`

This file contains both a self-signed certificate and the certificate's private key. Apache requires the certificate and key to be in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in the following abbreviated example.

```

The file names and extensions are a convenience and have no effect on function. For example, you can call a certificate `cert.crt`, `cert.pem`, or any other file name, so long as the related directive in the `ssl.conf` file uses the same name.

Note

When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

4. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

Note

Make sure that TCP port 443 is accessible on your EC2 instance, as previously described.

5. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by entering the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix `https://`.

Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings. Override the warnings and proceed to the site.

If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now encrypted.

Note

To prevent site visitors from encountering warning screens, you must obtain a trusted, CA-signed certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical. A CA promises, at a minimum, to validate a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a *chain of trust* consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the [Let's Encrypt](#) project, which also supports the automation of the certificate creation and renewal process. For more information about using Let's Encrypt as your CA, see [Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 \(p. 70\)](#).

If you plan to offer commercial-grade services, [AWS Certificate Manager](#) is a good option.

Underlying the host certificate is the key. As of 2019, [government](#) and [industry](#) groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents, through 2030. The default modulus size generated by OpenSSL in Amazon Linux 2022 is 2048 bits, which is suitable for use in a CA-signed certificate. In the following procedure, an optional step provided for those who want a customized key, for example, one with a larger modulus or using a different encryption algorithm.

Important

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

To obtain a CA-signed certificate

1. [Connect to your instance \(p. 11\)](#) and navigate to `/etc/pki/tls/private/`. This is the directory where you store the server's private key for TLS. If you prefer to use an existing host key to generate the CSR, skip to Step 3.
2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys works with your web server, but they vary in the degree and type of security that they implement.
 - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key
```

- **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
```

- **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, `custom.key`, is a 4096-bit RSA private key encrypted with the AES-128 cipher.

Important

Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

```
[ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
```

- **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

```
[ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
```

The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, [according to NIST](#).

Note

Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as shown in the following example.

```
[ec2-user ~]$ sudo chown root:root custom.key
[ec2-user ~]$ sudo chmod 600 custom.key
[ec2-user ~]$ ls -al custom.key
```

The preceding commands yield the following result.

```
-rw----- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key. The following example uses `custom.key`.

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

Name	Description	Example
Country Name	The two-letter ISO abbreviation for your country.	US (=United States)
State or Province Name	The name of the state or province where your organization is located. This name cannot be abbreviated.	Washington
Locality Name	The location of your organization, such as a city.	Seattle
Organization Name	The full legal name of your organization. Do not abbreviate your organization name.	Example Corporation
Organizational Unit Name	Additional organizational information, if any.	Example Dept
Common Name	This value must exactly match the web address that you expect users to enter into a browser. Usually, this means a domain	www.example.com

Name	Description	Example
	name with a prefixed hostname or alias in the form www.example.com . In testing with a self-signed certificate and no DNS resolution, the common name may consist of the hostname alone. CAs also offer more expensive certificates that accept wild-card names such as *.example.com .	
Email Address	The server administrator's email address.	someone@example.com

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file **csr.pem** contains your public key, your digital signature of your public key, and the metadata that you entered.

4. Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If **www.example.com** is the common name, then **example.com** would be a good SAN, and vice versa. A visitor to your site entering either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA's chain of trust.

Note

Your CA might send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a **.pem** or **.crt** file extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following line.

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following line.

```
- - - - -END CERTIFICATE - - - - -
```

You can also test the file at the command line as shown in the following.

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with **.p7b**, **.p7c**, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the **/etc/pki/tls/certs** directory.

Note

There are several ways to upload your new certificate to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste

the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/certs directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2022 defaults (owner=root, group=root, read/write for owner only). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

These commands should yield the following result.

```
-rw----- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root intermediate.crt
[ec2-user certs]$ sudo chmod 644 intermediate.crt
[ec2-user certs]$ ls -al intermediate.crt
```

These commands should yield the following result.

```
-rw-r--r-- root root intermediate.crt
```

6. Place the private key that you used to create the CSR in the /etc/pki/tls/private/ directory.

Note

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/private directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2022 defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user private]$ sudo chown root:root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ ls -al custom.key
```

These commands should yield the following result.

```
-rw----- root root custom.key
```

7. Edit /etc/httpd/conf.d/ssl.conf to reflect your new certificate and key files.

- a. Provide the path and file name of the CA-signed host certificate in Apache's SSLCertificateFile directive:

```
SSLCertificateFile /etc/pki/tls/certs/custom.crt
```

- b. If you received an intermediate certificate file (`intermediate.crt` in this example), provide its path and file name using Apache's `SSLCACertificateFile` directive:

```
SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
```

Note

Some CAs combine the host certificate and the intermediate certificates in a single file, making the `SSLCACertificateFile` directive unnecessary. Consult the instructions provided by your CA.

- c. Provide the path and file name of the private key (`custom.key` in this example) in Apache's `SSLCertificateKeyFile` directive:

```
SSLCertificateKeyFile /etc/pki/tls/private/custom.key
```

8. Save `/etc/httpd/conf.d/ssl.conf` and restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

9. Test your server by entering your domain name into a browser URL bar with the prefix `https://`. Your browser should load the test page over HTTPS without generating errors.

Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as [Qualys SSL Labs](#), which performs a free and thorough analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see [how Qualys formulates its scores](#).

Important

Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the [Qualys SSL Labs](#) site, enter the fully qualified domain name of your server, in the form `www.example.com`. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. The following table summarizes the report for a domain with settings identical to the default Apache configuration on Amazon Linux 2022, and with a default Certbot certificate.

Overall rating	B
Certificate	100%
Protocol support	95%
Key exchange	70%
Cipher strength	90%

Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems, listed here in order of severity:

X The RC4 cipher is supported for use by certain older browsers. A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several [serious weaknesses](#). Unless you have very good reasons to support legacy browsers, you should disable this.

X Old TLS versions are supported. The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

X Forward secrecy is not fully supported. [Forward secrecy](#) is a feature of algorithms that encrypt using temporary (ephemeral) session keys derived from the private key. This means in practice that attackers cannot decrypt HTTPS data even if they possess a web server's long-term private key.

To correct and future-proof the TLS configuration

1. Open the configuration file `/etc/httpd/conf.d/ssl.conf` in a text editor and comment out the following line by entering "#" at the beginning of the line.

```
#SSLProtocol all -SSLv3
```

2. Add the following directive:

```
#SSLProtocol all -SSLv3
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

This directive explicitly disables SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive conveys more clearly, to a human reader, what the server is configured to do.

Note

Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. In the configuration file `/etc/httpd/conf.d/ssl.conf`, find the section with the `SSLCipherSuite` directive and comment out the existing line by entering "#" at the beginning of the line.

```
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

2. Specify explicit cipher suites and a cipher order that prioritizes forward secrecy and avoids insecure ciphers. The `SSLCipherSuite` directive used here is based on output from the [Mozilla SSL Configuration Generator](#), which tailors a TLS configuration to the specific software running on your server. (For more information, see Mozilla's useful resource [Security/Server Side TLS](#).) First determine your Apache and OpenSSL versions by using the output from the following commands.

```
[ec2-user ~]$ yum list installed | grep httpd
[ec2-user ~]$ yum list installed | grep openssl
```

For example, if the returned information is Apache 2.4.34 and OpenSSL 1.0.2, we enter this into the generator. If you choose the "modern" compatibility model, this creates an `SSLCipherSuite` directive that aggressively enforces security but still works for most browsers. If your software

doesn't support the modern configuration, you can update your software or choose the "intermediate" configuration instead.

```
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-  
CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:  
ECDHE-ECDSA-AES256-SHA384:ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-  
AES128-SHA256
```

The selected ciphers have *ECDHE* in their names, an abbreviation for *Elliptic Curve Diffie-Hellman Ephemeral*. The term *ephemeral* indicates forward secrecy. As a by-product, these ciphers do not support RC4.

We recommend that you use an explicit list of ciphers instead of relying on defaults or terse directives whose content isn't visible.

Copy the generated directive into `/etc/httpd/conf.d/ssl.conf`.

Note

Though shown here on several lines for readability, the directive must be on a single line when copied to `/etc/httpd/conf.d/ssl.conf`, with only a colon (no spaces) between cipher names.

- Finally, uncomment the following line by removing the "#" at the beginning of the line.

```
#SSLHonorCipherOrder on
```

This directive forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strong secure connection before falling back to allowed ciphers with lesser security.

After completing both of these procedures, save the changes to `/etc/httpd/conf.d/ssl.conf` and restart Apache.

If you test the domain again on [Qualys SSL Labs](#), you should see that the RC4 vulnerability and other warnings are gone and the summary looks something like the following.

Overall rating	A
Certificate	100%
Protocol support	100%
Key exchange	90%
Cipher strength	90%

Each update to OpenSSL introduces new ciphers and removes support for old ones. Keep your EC2 Amazon Linux 2022 instance up-to-date, watch for security announcements from [OpenSSL](#), and be alert to reports of new security exploits in the technical press.

Troubleshoot

- My Apache webserver doesn't start unless I enter a password**

This is expected behavior if you installed an encrypted, password-protected, private server key.

You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/  
[ec2-user private]$ sudo cp custom.key custom.key.bak  
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out  
    custom.key.nocrypt  
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key  
[ec2-user private]$ sudo chown root:root custom.key  
[ec2-user private]$ sudo chmod 600 custom.key  
[ec2-user private]$ sudo systemctl restart httpd
```

Apache should now start without prompting you for a password.

- **I get errors when I run `sudo dnf install -y mod_ssl`.**

When you are installing the required packages for SSL, you may see errors similar to the following.

```
Error: httpd24-tools conflicts with httpd-tools-2.2.34-1.16.amzn1.x86_64  
Error: httpd24 conflicts with httpd-2.2.34-1.16.amzn1.x86_64
```

This typically means that your EC2 instance is not running Amazon Linux 2022. This tutorial only supports instances freshly created from an official Amazon Linux 2022 AMI.

Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2022

Warning

Let's Encrypt cross-signed DST Root CA X3 certificate expired on **Sept 30th, 2021**. This can cause Let's Encrypt connections to fail with OpenSSL 1.0.x on CentOS/RHEL7 and Amazon Linux. Remediation steps can be found [here](#), or you can follow one of the manual workarounds found on the [OpenSSL blog page](#).

Important

These instructions for acquiring a Let's Encrypt host certificate do not work unless you own a registered and hosted DNS domain. These instructions do not work with the public DNS hostnames assigned by AWS.

The [Let's Encrypt](#) certificate authority is the centerpiece of an effort by the Electronic Frontier Foundation (EFF) to encrypt the entire internet. In line with that goal, Let's Encrypt host certificates are designed to be created, validated, installed, and maintained with minimal human intervention. The automated aspects of certificate management are carried out by a software agent running on your web server. After you install and configure the agent, it communicates securely with Let's Encrypt and performs administrative tasks on Apache and the key management system. This tutorial uses the free [Certbot](#) agent because it allows you either to supply a customized encryption key as the basis for your certificates, or to allow the agent itself to create a key based on its defaults. You can also configure Certbot to renew your certificates on a regular basis without human interaction, as described in [To automate Certbot \(p. 58\)](#). For more information, consult the Certbot [User Guide](#) and [man page](#).

Certbot is not officially supported on Amazon Linux 2022, but is available for download and functions correctly when installed. We recommend that you make the following backups to protect your data and avoid inconvenience:

- Before you begin, take a snapshot of your Amazon EBS root volume. This allows you to restore the original state of your EC2 instance. For information about creating EBS snapshots, see [Create Amazon EBS snapshots \(p. 1407\)](#).
- The procedure below requires you to edit your `httpd.conf` file, which controls Apache's operation. Certbot makes its own automated changes to this and other configuration files. Make a backup copy of your entire `/etc/httpd` directory in case you need to restore it.

Prepare to install

Complete the following procedures before you install Certbot.

1. Download the Extra Packages for Enterprise Linux (EPEL) 7 repository packages. These are required to supply dependencies needed by Certbot.

- a. Navigate to your home directory (`/home/ec2-user`). Download and install these packages using the following command.

```
[ec2-user ~]$ sudo dnf install -y python3 augeas-libs pip
```

- b. Execute the following instructions on the command line on the machine to set up a Python virtual environment.

```
sudo python3 -m venv /opt/certbot/
```

- c. Install the latest version of pip.

```
[ec2-user ~]$ sudo /opt/certbot/bin/pip install --upgrade pip
```

Install certbot.

```
[ec2-user ~]$ sudo /opt/certbot/bin/pip install certbot
```

A a symbolic link.

```
[ec2-user ~]$ sudo ln -s /opt/certbot/bin/certbot /usr/bin/certbot
```

2. You will need to stop http before the next step.

```
sudo systemctl stop httpd
```

If you cannot stop your web server, alternatively you can use the following command.

```
[ec2-user ~]$ sudo certbot certonly --webroot
```

Run Certbot

This procedure is based on the EFF documentation for installing Certbot on [Fedora](#) and on [RHEL 7](#). It describes the default use of Certbot, resulting in a certificate based on a 2048-bit RSA key.

1. Run Certbot.

```
[ec2-user ~]$ sudo certbot certonly --standalone
```

IMPORTANT NOTES:

- Congratulations! Your certificate and chain have been saved at:
`/etc/letsencrypt/live/certbot.oneeyedman.net/fullchain.pem`
Your key file has been saved at:
`/etc/letsencrypt/live/certbot.oneeyedman.net/privkey.pem`
Your cert will expire on 2019-08-01. To obtain a new or tweaked
version of this certificate in the future, simply run certbot again
with the "certonly" option. To non-interactively renew *all* of
your certificates, run "certbot renew"
- Your account credentials have been saved in your Certbot
configuration directory at `/etc/letsencrypt`. You should make a
secure backup of this folder now. This configuration directory will
also contain certificates and private keys obtained by Certbot so
making regular backups of this folder is ideal.

8. After you complete the installation, test and optimize the security of your server as described in [Step 3: Test and harden the security configuration \(p. 52\)](#).

Configure automated certificate renewal

Certbot is designed to become an invisible, error-resistant part of your server system. By default, it generates host certificates with a short, 90-day expiration time. If you have not configured your system to call the command automatically, you must re-run the `certbot` command manually before expiration. This procedure shows how to automate Certbot by setting up a cron job.

To automate Certbot

1. Open the `/etc/crontab` file in a text editor, such as `vim` or `nano`, using `sudo`. Alternatively, use `sudo crontab -e`.
2. Add a line similar to the following and save the file.

```
39      1,13    *      *      *      root    certbot renew --no-self-upgrade
```

Here is an explanation of each component:

```
39 1,13 * * *
```

Schedules a command to be run at 01:39 and 13:39 every day. The selected values are arbitrary, but the Certbot developers suggest running the command at least twice daily. This guarantees that any certificate found to be compromised is promptly revoked and replaced.

```
root
```

The command runs with root permissions.

```
certbot renew --no-self-upgrade
```

The command to be run. The `renew` subcommand causes Certbot to check any previously obtained certificates and to renew those that are approaching expiration. The `--no-self-upgrade` flag prevents Certbot from upgrading itself without your intervention.

3. Restart the cron daemon.

```
[ec2-user ~]$ sudo systemctl restart crond
```

Tutorial: Configure SSL/TLS on Amazon Linux 2

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with Amazon Linux 2 and Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from [AWS Certificate Manager](#) instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. Amazon Linux 2 disables server-side support for all versions of SSL by default. [Security standards bodies](#) consider TLS 1.0 to be unsafe, and both TLS 1.0 and TLS 1.1 are on track to be formally [deprecated](#) by the IETF. This tutorial contains guidance based exclusively on enabling TLS 1.2. (A newer TLS 1.3 protocol exists, but it is not installed by default on Amazon Linux 2.) For more information about the updated encryption standards, see [RFC 7568](#) and [RFC 8446](#).

This tutorial refers to modern web encryption simply as TLS.

Important

These procedures are intended for use with Amazon Linux 2. We also assume that you are starting with a new Amazon EC2 instance. If you are trying to set up an EC2 instance running a different distribution, or an instance running an old version of Amazon Linux 2, some procedures in this tutorial might not work. For the Amazon Linux AMI, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI \(p. 74\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For Red Hat Enterprise Linux, see the following: [Setting up the Apache HTTP Web Server](#). For other distributions, see their specific documentation.

Note

Alternatively, you can use AWS Certificate Manager (ACM) for AWS Nitro enclaves, which is an enclave application that allows you to use public and private SSL/TLS certificates with your web applications and servers running on Amazon EC2 instances with AWS Nitro Enclaves. Nitro Enclaves is an Amazon EC2 capability that enables creation of isolated compute environments to protect and securely process highly sensitive data, such as SSL/TLS certificates and private keys. ACM for Nitro Enclaves works with [nginx](#) running on your Amazon EC2 Linux instance to create private keys, to distribute certificates and private keys, and to manage certificate renewals. To use ACM for Nitro Enclaves, you must use an enclave-enabled Linux instance. For more information, see [What is AWS Nitro Enclaves?](#) and [AWS Certificate Manager for Nitro Enclaves](#) in the [AWS Nitro Enclaves User Guide](#).

- [Troubleshoot \(p. 69\)](#)
- [Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 \(p. 70\)](#)

Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed Amazon Linux 2 instance. For more information, see [Step 1: Launch an instance \(p. 10\)](#).

- Configure your security groups to allow your instance to accept connections on the following TCP ports:
 - SSH (port 22)
 - HTTP (port 80)
 - HTTPS (port 443)

For more information, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

- Install the Apache web server. For step-by-step instructions, see [Tutorial: Install a LAMP Web Server on Amazon Linux 2 \(p. 25\)](#). Only the httpd package and its dependencies are needed, so you can ignore the instructions involving PHP and MariaDB.
- To identify and authenticate websites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public website, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use [Amazon Route 53](#).

Step 1: Enable TLS on the server

This procedure takes you through the process of setting up TLS on Amazon Linux 2 with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site are greeted by security warnings.

To enable TLS on a server

- Connect to your instance (p. 11) and confirm that Apache is running.

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the returned value is not "enabled," start Apache and set it to start each time the system boots.

```
[ec2-user ~]$ sudo systemctl start httpd && sudo systemctl enable httpd
```

- To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

Note

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

- Now that your instance is current, add TLS support by installing the Apache module `mod_ssl`.

```
[ec2-user ~]$ sudo yum install -y mod_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

- `/etc/httpd/conf.d/ssl.conf`

The configuration file for mod_ssl. It contains *directives* telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

- `/etc/pki/tls/certs/make-dummy-cert`

A script to generate a self-signed X.509 certificate and private key for your server host. This certificate is useful for testing that Apache is properly set up to use TLS. Because it offers no proof of identity, it should not be used in production. If used in production, it triggers warnings in Web browsers.

4. Run the script to generate a self-signed dummy certificate and key for testing.

```
[ec2-user ~]$ cd /etc/pki/tls/certs  
sudo ./make-dummy-cert localhost.crt
```

This generates a new file `localhost.crt` in the `/etc/pki/tls/certs/` directory. The specified file name matches the default that is assigned in the `SSLCertificateFile` directive in `/etc/httpd/conf.d/ssl.conf`.

This file contains both a self-signed certificate and the certificate's private key. Apache requires the certificate and key to be in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in the following abbreviated example.

```
-----BEGIN PRIVATE KEY-----

3ZazhBxtQSukFMOonWPP2a0DMMFGYUH0d0BQE8sBJxg==  
-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function. For example, you can call a certificate `cert.crt`, `cert.pem`, or any other file name, so long as the related directive in the `ssl.conf` file uses the same name.

Note

When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

5. Open the `/etc/httpd/conf.d/ssl.conf` file using your favorite text editor (such as `vim` or `nano`) and comment out the following line, because the self-signed dummy certificate also contains the key. If you do not comment out this line before you complete the next step, the Apache service fails to start.

```
SSLCertificateKeyFile /etc/pki/tls/private/localhost.key
```

6. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

Note

Make sure that TCP port 443 is accessible on your EC2 instance, as previously described.

7. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by entering the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix **https://**.

Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings. Override the warnings and proceed to the site.

If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now encrypted.

Note

To prevent site visitors from encountering warning screens, you must obtain a trusted, CA-signed certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical. A CA promises, at a minimum, to validate a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a *chain of trust* consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the [Let's Encrypt](#) project, which also supports the automation of the certificate creation and renewal process. For more information about using Let's Encrypt as your CA, see [Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 \(p. 70\)](#).

If you plan to offer commercial-grade services, [AWS Certificate Manager](#) is a good option.

Underlying the host certificate is the key. As of 2019, [government](#) and [industry](#) groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents, through 2030. The default modulus size generated by OpenSSL in Amazon Linux 2 is 2048 bits, which is suitable for use

in a CA-signed certificate. In the following procedure, an optional step provided for those who want a customized key, for example, one with a larger modulus or using a different encryption algorithm.

Important

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

To obtain a CA-signed certificate

1. [Connect to your instance \(p. 11\)](#) and navigate to `/etc/pki/tls/private/`. This is the directory where you store the server's private key for TLS. If you prefer to use an existing host key to generate the CSR, skip to Step 3.
2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys works with your web server, but they vary in the degree and type of security that they implement.
 - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key
```

- **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
```

- **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, `custom.key`, is a 4096-bit RSA private key encrypted with the AES-128 cipher.

Important

Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

```
[ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
```

- **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

```
[ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
```

The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, [according to NIST](#).

Note

Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as shown in the following example.

```
[ec2-user ~]$ sudo chown root:root custom.key
[ec2-user ~]$ sudo chmod 600 custom.key
[ec2-user ~]$ ls -al custom.key
```

The preceding commands yield the following result.

```
-rw----- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key. The following example uses **custom.key**.

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

Name	Description	Example
Country Name	The two-letter ISO abbreviation for your country.	US (=United States)
State or Province Name	The name of the state or province where your organization is located. This name cannot be abbreviated.	Washington
Locality Name	The location of your organization, such as a city.	Seattle
Organization Name	The full legal name of your organization. Do not abbreviate your organization name.	Example Corporation
Organizational Unit Name	Additional organizational information, if any.	Example Dept
Common Name	This value must exactly match the web address that you expect users to enter into a browser. Usually, this means a domain name with a prefixed hostname or alias in the form www.example.com . In testing with a self-signed certificate and no DNS resolution, the common name may consist of the hostname alone. CAs also offer more expensive certificates that accept wild-card names such as *.example.com .	www.example.com
Email Address	The server administrator's email address.	someone@example.com

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file **csr.pem** contains your public key, your digital signature of your public key, and the metadata that you entered.

4. Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If `www.example.com` is the common name, then `example.com` would be a good SAN, and vice versa. A visitor to your site entering either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA's chain of trust.

Note

Your CA might send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a `.pem` or `.crt` file extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following line.

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following line.

```
- - - - -END CERTIFICATE - - - - -
```

You can also test the file at the command line as shown in the following.

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with `.p7b`, `.p7c`, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the `/etc/pki/tls/certs` directory.

Note

There are several ways to upload your new certificate to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the `/etc/pki/tls/certs` directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (`owner=root`, `group=root`, `read/write for owner only`). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

These commands should yield the following result.

```
-rw----- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root intermediate.crt
[ec2-user certs]$ sudo chmod 644 intermediate.crt
[ec2-user certs]$ ls -al intermediate.crt
```

These commands should yield the following result.

```
-rw-r--r-- root root intermediate.crt
```

6. Place the private key that you used to create the CSR in the /etc/pki/tls/private/ directory.

Note

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/private directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user private]$ sudo chown root:root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ ls -al custom.key
```

These commands should yield the following result.

```
-rw----- root root custom.key
```

7. Edit /etc/httpd/conf.d/ssl.conf to reflect your new certificate and key files.

- a. Provide the path and file name of the CA-signed host certificate in Apache's SSLCertificateFile directive:

```
SSLCertificateFile /etc/pki/tls/certs/custom.crt
```

- b. If you received an intermediate certificate file (intermediate.crt in this example), provide its path and file name using Apache's SSLCACertificateFile directive:

```
SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
```

Note

Some CAs combine the host certificate and the intermediate certificates in a single file, making the SSLCACertificateFile directive unnecessary. Consult the instructions provided by your CA.

- c. Provide the path and file name of the private key (custom.key in this example) in Apache's SSLCertificateKeyFile directive:

```
SSLCertificateKeyFile /etc/pki/tls/private/custom.key
```

8. Save /etc/httpd/conf.d/ssl.conf and restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

9. Test your server by entering your domain name into a browser URL bar with the prefix https://. Your browser should load the test page over HTTPS without generating errors.

Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as [Qualys SSL Labs](#), which performs a free and thorough analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see [how Qualys formulates its scores](#).

Important

Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the [Qualys SSL Labs](#) site, enter the fully qualified domain name of your server, in the form `www.example.com`. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. The following table summarizes the report for a domain with settings identical to the default Apache configuration on Amazon Linux 2, and with a default Certbot certificate.

Overall rating	B
Certificate	100%
Protocol support	95%
Key exchange	70%
Cipher strength	90%

Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems, listed here in order of severity:

X The RC4 cipher is supported for use by certain older browsers. A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several [serious weaknesses](#). Unless you have very good reasons to support legacy browsers, you should disable this.

X Old TLS versions are supported. The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

X Forward secrecy is not fully supported. [Forward secrecy](#) is a feature of algorithms that encrypt using temporary (ephemeral) session keys derived from the private key. This means in practice that attackers cannot decrypt HTTPS data even if they possess a web server's long-term private key.

To correct and future-proof the TLS configuration

1. Open the configuration file /etc/httpd/conf.d/ssl.conf in a text editor and comment out the following line by entering "#" at the beginning of the line.

```
#SSLProtocol all -SSLv3
```

2. Add the following directive:

```
#SSLProtocol all -SSLv3  
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

This directive explicitly disables SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive conveys more clearly, to a human reader, what the server is configured to do.

Note

Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. In the configuration file `/etc/httpd/conf.d/ssl.conf`, find the section with the `SSLCipherSuite` directive and comment out the existing line by entering "#" at the beginning of the line.

```
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

2. Specify explicit cipher suites and a cipher order that prioritizes forward secrecy and avoids insecure ciphers. The `SSLCipherSuite` directive used here is based on output from the [Mozilla SSL Configuration Generator](#), which tailors a TLS configuration to the specific software running on your server. (For more information, see Mozilla's useful resource [Security/Server Side TLS](#).) First determine your Apache and OpenSSL versions by using the output from the following commands.

```
[ec2-user ~]$ yum list installed | grep httpd  
[ec2-user ~]$ yum list installed | grep openssl
```

For example, if the returned information is Apache 2.4.34 and OpenSSL 1.0.2, we enter this into the generator. If you choose the "modern" compatibility model, this creates an `SSLCipherSuite` directive that aggressively enforces security but still works for most browsers. If your software doesn't support the modern configuration, you can update your software or choose the "intermediate" configuration instead.

```
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-  
CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:  
ECDHE-ECDSA-AES256-SHA384:ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-  
AES128-SHA256
```

The selected ciphers have *ECDHE* in their names, an abbreviation for *Elliptic Curve Diffie-Hellman Ephemeral*. The term *ephemeral* indicates forward secrecy. As a by-product, these ciphers do not support RC4.

We recommend that you use an explicit list of ciphers instead of relying on defaults or terse directives whose content isn't visible.

Copy the generated directive into `/etc/httpd/conf.d/ssl.conf`.

Note

Though shown here on several lines for readability, the directive must be on a single line when copied to `/etc/httpd/conf.d/ssl.conf`, with only a colon (no spaces) between cipher names.

- Finally, uncomment the following line by removing the "#" at the beginning of the line.

```
#SSLHonorCipherOrder on
```

This directive forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strong secure connection before falling back to allowed ciphers with lesser security.

After completing both of these procedures, save the changes to `/etc/httpd/conf.d/ssl.conf` and restart Apache.

If you test the domain again on [Qualys SSL Labs](#), you should see that the RC4 vulnerability and other warnings are gone and the summary looks something like the following.

Overall rating	A
Certificate	100%
Protocol support	100%
Key exchange	90%
Cipher strength	90%

Each update to OpenSSL introduces new ciphers and removes support for old ones. Keep your EC2 Amazon Linux 2 instance up-to-date, watch for security announcements from [OpenSSL](#), and be alert to reports of new security exploits in the technical press.

Troubleshoot

- My Apache webserver doesn't start unless I enter a password**

This is expected behavior if you installed an encrypted, password-protected, private server key.

You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/
[ec2-user private]$ sudo cp custom.key custom.key.bak
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out
    custom.key.nocrypt
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key
[ec2-user private]$ sudo chown root:root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ sudo systemctl restart httpd
```

Apache should now start without prompting you for a password.

- I get errors when I run `sudo yum install -y mod_ssl`.**

When you are installing the required packages for SSL, you may see errors similar to the following.

```
Error: httpd24-tools conflicts with httpd-tools-2.2.34-1.16.amzn1.x86_64
Error: httpd24 conflicts with httpd-2.2.34-1.16.amzn1.x86_64
```

This typically means that your EC2 instance is not running Amazon Linux 2. This tutorial only supports instances freshly created from an official Amazon Linux 2 AMI.

Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2

Warning

Let's Encrypt cross-signed DST Root CA X3 certificate **expired on Sept 30th, 2021**. This can cause Let's Encrypt connections to fail with OpenSSL 1.0.x on CentOS/RHEL7 and Amazon Linux. Remediation steps can be found [here](#), or you can follow one of the manual workarounds found on the [OpenSSL blog page](#).

Important

These instructions for acquiring a Let's Encrypt host certificate do not work unless you own a registered and hosted DNS domain. These instructions do not work with the public DNS hostnames assigned by AWS.

The [Let's Encrypt](#) certificate authority is the centerpiece of an effort by the Electronic Frontier Foundation (EFF) to encrypt the entire internet. In line with that goal, Let's Encrypt host certificates are designed to be created, validated, installed, and maintained with minimal human intervention. The automated aspects of certificate management are carried out by a software agent running on your web server. After you install and configure the agent, it communicates securely with Let's Encrypt and performs administrative tasks on Apache and the key management system. This tutorial uses the free [Certbot](#) agent because it allows you either to supply a customized encryption key as the basis for your certificates, or to allow the agent itself to create a key based on its defaults. You can also configure Certbot to renew your certificates on a regular basis without human interaction, as described in [To automate Certbot \(p. 73\)](#). For more information, consult the Certbot [User Guide](#) and [man page](#).

Certbot is not officially supported on Amazon Linux 2, but is available for download and functions correctly when installed. We recommend that you make the following backups to protect your data and avoid inconvenience:

- Before you begin, take a snapshot of your Amazon EBS root volume. This allows you to restore the original state of your EC2 instance. For information about creating EBS snapshots, see [Create Amazon EBS snapshots \(p. 1407\)](#).
- The procedure below requires you to edit your `httpd.conf` file, which controls Apache's operation. Certbot makes its own automated changes to this and other configuration files. Make a backup copy of your entire `/etc/httpd` directory in case you need to restore it.

Prepare to install

Complete the following procedures before you install Certbot.

1. Download the Extra Packages for Enterprise Linux (EPEL) 7 repository packages. These are required to supply dependencies needed by Certbot.
 - a. Navigate to your home directory (`/home/ec2-user`). Download EPEL using the following command.

```
[ec2-user ~]$ sudo wget -r --no-parent -A 'epel-release-*' https://dl.fedoraproject.org/pub/epel/7/x86_64/Packages/e/
```

- b. Install the repository packages as shown in the following command.

```
[ec2-user ~]$ sudo rpm -Uvh dl.fedoraproject.org/pub/epel/7/x86_64/Packages/e/epel-release-*.rpm
```

- c. Enable EPEL as shown in the following command.

```
[ec2-user ~]$ sudo yum-config-manager --enable epel*
```

You can confirm that EPEL is enabled with the following command.

```
[ec2-user ~]$ sudo yum repolist all
```

It should return information similar to the following.

```
[ec2-user ~]$  
...  
epel/x86_64          Extra Packages for Enterprise Linux 7 - x86_64  
enabled: 12949+175  
epel-debuginfo/x86_64 Extra Packages for Enterprise Linux 7 - x86_64  
enabled: 2890  
epel-source/x86_64   Extra Packages for Enterprise Linux 7 - x86_64  
enabled: 0  
epel-testing/x86_64  Extra Packages for Enterprise Linux 7 -  
Testing - x86_64     enabled: 778+12  
epel-testing-debuginfo/x86_64 Extra Packages for Enterprise Linux 7 -  
Testing - x86_64 - Debug enabled: 107  
epel-testing-source/x86_64 Extra Packages for Enterprise Linux 7 -  
Testing - x86_64 - Source enabled: 0  
...
```

2. Edit the main Apache configuration file, /etc/httpd/conf/httpd.conf. Locate the "Listen 80" directive and add the following lines after it, replacing the example domain names with the actual Common Name and Subject Alternative Name (SAN).

```
<VirtualHost *:80>  
    DocumentRoot "/var/www/html"  
    ServerName "example.com"  
    ServerAlias "www.example.com"  
</VirtualHost>
```

Save the file and restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

Install and run Certbot

This procedure is based on the EFF documentation for installing Certbot on [Fedora](#) and on [RHEL 7](#). It describes the default use of Certbot, resulting in a certificate based on a 2048-bit RSA key.

1. Install the Amazon Extras repo for epel.

Amazon Elastic Compute Cloud
User Guide for Linux Instances
Certificate automation: Let's Encrypt
with Certbot on Amazon Linux 2

```
[ec2-user ~]$ sudo amazon-linux-extras install epel -y
```

2. Install Certbot packages and dependencies using the following command.

```
[ec2-user ~]$ sudo yum install -y certbot python2-certbot-apache
```

3. Run Certbot.

```
[ec2-user ~]$ sudo certbot
```

4. At the prompt "Enter email address (used for urgent renewal and security notices)," enter a contact address and press Enter.
5. Agree to the Let's Encrypt Terms of Service at the prompt. Enter "A" and press Enter to proceed.

```
-----  
Please read the Terms of Service at  
https://letsencrypt.org/documents/LE-SA-v1.2-November-15-2017.pdf. You must  
agree in order to register with the ACME server at  
https://acme-v02.api.letsencrypt.org/directory  
-----  
(A)gree/(C)ancel: A
```

6. At the authorization for EFF to put you on their mailing list, enter "Y" or "N" and press Enter.
7. Certbot displays the Common Name and Subject Alternative Name (SAN) that you provided in the VirtualHost block.

```
Which names would you like to activate HTTPS for?  
-----  
1: example.com  
2: www.example.com  
-----  
Select the appropriate numbers separated by commas and/or spaces, or leave input  
blank to select all options shown (Enter 'c' to cancel):
```

Leave the input blank and press Enter.

8. Certbot displays the following output as it creates certificates and configures Apache. It then prompts you about redirecting HTTP queries to HTTPS.

```
Obtaining a new certificate  
Performing the following challenges:  
http-01 challenge for example.com  
http-01 challenge for www.example.com  
Waiting for verification...  
Cleaning up challenges  
Created an SSL vhost at /etc/httpd/conf/httpd-le-ssl.conf  
Deploying Certificate for example.com to VirtualHost /etc/httpd/conf/httpd-le-ssl.conf  
Enabling site /etc/httpd/conf/httpd-le-ssl.conf by adding Include to root configuration  
Deploying Certificate for www.example.com to VirtualHost /etc/httpd/conf/httpd-le-ssl.conf  
  
Please choose whether or not to redirect HTTP traffic to HTTPS, removing HTTP access.  
-----  
1: No redirect - Make no further changes to the webserver configuration.  
2: Redirect - Make all requests redirect to secure HTTPS access. Choose this for  
new sites, or if you're confident your site works on HTTPS. You can undo this  
change by editing your web server's configuration.  
-----  
Select the appropriate number [1-2] then [enter] (press 'c' to cancel):
```

To allow visitors to connect to your server via unencrypted HTTP, enter "1". If you want to accept only encrypted connections via HTTPS, enter "2". Press Enter to submit your choice.

9. Certbot completes the configuration of Apache and reports success and other information.

```
Congratulations! You have successfully enabled https://example.com and  
https://www.example.com
```

```
You should test your configuration at:
```

```
https://www.ssllabs.com/ssltest/analyze.html?d=example.com  
https://www.ssllabs.com/ssltest/analyze.html?d=www.example.com
```

IMPORTANT NOTES:

- Congratulations! Your certificate and chain have been saved at:
`/etc/letsencrypt/live/certbot.oneeyedman.net/fullchain.pem`
Your key file has been saved at:
`/etc/letsencrypt/live/certbot.oneeyedman.net/privkey.pem`
Your cert will expire on 2019-08-01. To obtain a new or tweaked
version of this certificate in the future, simply run certbot again
with the "certonly" option. To non-interactively renew *all* of
your certificates, run "certbot renew"
- Your account credentials have been saved in your Certbot
configuration directory at `/etc/letsencrypt`. You should make a
secure backup of this folder now. This configuration directory will
also contain certificates and private keys obtained by Certbot so
making regular backups of this folder is ideal.

10. After you complete the installation, test and optimize the security of your server as described in [Step 3: Test and harden the security configuration \(p. 67\)](#).

Configure automated certificate renewal

Certbot is designed to become an invisible, error-resistant part of your server system. By default, it generates host certificates with a short, 90-day expiration time. If you have not configured your system to call the command automatically, you must re-run the `certbot` command manually before expiration. This procedure shows how to automate Certbot by setting up a cron job.

To automate Certbot

1. Open the `/etc/crontab` file in a text editor, such as `vim` or `nano`, using `sudo`. Alternatively, use `sudo crontab -e`.
2. Add a line similar to the following and save the file.

```
39      1,13    *      *      *      root    certbot renew --no-self-upgrade
```

Here is an explanation of each component:

```
39 1,13 * * *
```

Schedules a command to be run at 01:39 and 13:39 every day. The selected values are arbitrary, but the Certbot developers suggest running the command at least twice daily. This guarantees that any certificate found to be compromised is promptly revoked and replaced.

```
root
```

The command runs with root permissions.

```
certbot renew --no-self-upgrade
```

The command to be run. The **renew** subcommand causes Certbot to check any previously obtained certificates and to renew those that are approaching expiration. The **--no-self-upgrade** flag prevents Certbot from upgrading itself without your intervention.

3. Restart the cron daemon.

```
[ec2-user ~]$ sudo systemctl restart crond
```

Tutorial: Configure SSL/TLS with the Amazon Linux AMI

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with the Amazon Linux AMI and Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from [AWS Certificate Manager](#) instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. The Amazon Linux AMI disables server-side support all versions of SSL by default. [Security standards bodies](#) consider TLS 1.0 to be unsafe, and both TLS 1.0 and TLS 1.1 are on track to be formally [deprecated](#) by the IETF. This tutorial contains guidance based exclusively on enabling TLS 1.2. (A newer TLS 1.3 protocol exists in draft form, but is not supported on Amazon Linux.) For more information about the updated encryption standards, see [RFC 7568](#) and [RFC 8446](#).

This tutorial refers to modern web encryption simply as TLS.

Important

These procedures are intended for use with the Amazon Linux AMI. If you are trying to set up a LAMP web server on an instance with a different distribution, some procedures in this tutorial might not work for you. For Amazon Linux 2, see [Tutorial: Configure SSL/TLS on Amazon Linux 2 \(p. 59\)](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For Red Hat Enterprise Linux, see the following: [Setting up the Apache HTTP Web Server](#). For other distributions, see their specific documentation.

Note

Alternatively, you can use AWS Certificate Manager (ACM) for AWS Nitro enclaves, which is an enclave application that allows you to use public and private SSL/TLS certificates with your web applications and servers running on Amazon EC2 instances with AWS Nitro Enclaves. Nitro Enclaves is an Amazon EC2 capability that enables creation of isolated compute environments to protect and securely process highly sensitive data, such as SSL/TLS certificates and private keys. ACM for Nitro Enclaves works with [nginx](#) running on your Amazon EC2 Linux instance to create private keys, to distribute certificates and private keys, and to manage certificate renewals. To use ACM for Nitro Enclaves, you must use an enclave-enabled Linux instance.

For more information, see [What is AWS Nitro Enclaves?](#) and [AWS Certificate Manager for Nitro Enclaves](#) in the [AWS Nitro Enclaves User Guide](#).

- [Prerequisites \(p. 75\)](#)
- [Step 1: Enable TLS on the server \(p. 75\)](#)
- [Step 2: Obtain a CA-signed certificate \(p. 77\)](#)
- [Step 3: Test and harden the security configuration \(p. 81\)](#)

- [Troubleshoot \(p. 83\)](#)

Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed instance using the Amazon Linux AMI. For more information, see [Step 1: Launch an instance \(p. 10\)](#).
- Configure your security group to allow your instance to accept connections on the following TCP ports:
 - SSH (port 22)
 - HTTP (port 80)
 - HTTPS (port 443)

For more information, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

- Install Apache web server. For step-by-step instructions, see [Tutorial: Installing a LAMP Web Server on Amazon Linux \(p. 35\)](#). Only the http24 package and its dependencies are needed; you can ignore the instructions involving PHP and MySQL.
- To identify and authenticate web sites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public web site, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use [Amazon Route 53](#).

Step 1: Enable TLS on the server

This procedure takes you through the process of setting up TLS on Amazon Linux with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site receive security warnings.

To enable TLS on a server

1. [Connect to your instance \(p. 11\)](#) and confirm that Apache is running.

```
[ec2-user ~]$ sudo service httpd status
```

If necessary, start Apache.

```
[ec2-user ~]$ sudo service httpd start
```

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure you have the latest security updates and bug fixes.

Note

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, add TLS support by installing the Apache module `mod_ssl`:

```
[ec2-user ~]$ sudo yum install -y mod24_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

/etc/httpd/conf.d/ssl.conf

The configuration file for mod_ssl. It contains "directives" telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

/etc/pki/tls/private/localhost.key

An automatically generated, 2048-bit RSA private key for your Amazon EC2 host. During installation, OpenSSL used this key to generate a self-signed host certificate, and you can also use this key to generate a certificate signing request (CSR) to submit to a certificate authority (CA).

/etc/pki/tls/certs/localhost.crt

An automatically generated, self-signed X.509 certificate for your server host. This certificate is useful for testing that Apache is properly set up to use TLS.

The .key and .crt files are both in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in this abbreviated example of a certificate:

```
-----BEGIN CERTIFICATE-----  
MIIEazCCA1OgAwIBAgICWxQwDQYJKoZIhvcNAQELBQAwgbExCzAJBgNVBAYTAi0t  
MRIwEAYDVQQIDA1Tb21lU3RhGUxETAPBgNVBAcMCFNvbWVDaXR5MRkwFwYDVQQK  
DBBTb21lT3JnYW5pemF0aW9uMR8wHQYDVQQLDBZTb21lT3JnYW5pemF0aW9uYWxV  
bmlOMRkwFwYDVQODDBBpcC0xNzItMzEtMjAtMjM2MSQwIgYJKoZIhvcNAQkBFhV  
...  
z5rRUE/XzxRLBZooWZpNWTXJkQ3uFYH6s/sBwtHpKKZMzOvDedREjNKAvk4ws6F0  
WanXWehT6FisZvB4sTEXXJN2jdw8g+sHGNz8zC0sclknYhHrCVD2vnBlZJKSzvak  
3ZazhBxtQSukFMOonWPP2a0DMMFGYUHod0BQE8sBJxg==  
-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function; you can call a certificate cert.crt, cert.pem, or any other file name, so long as the related directive in the ssl.conf file uses the same name.

Note

When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

4. Restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
```

5. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by typing the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix **https://**. Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings.

Override the warnings and proceed to the site. If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now safely encrypted.

To prevent site visitors from encountering warning screens, you need to obtain a certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical; a CA promises to validate, at a minimum, a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a chain of trust consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the [Let's Encrypt](#) project, which also supports the automation of the certificate creation and renewal process. For more information about using Let's Encrypt as your CA, see [Certificate automation: Let's Encrypt with Certbot on Amazon Linux 2 \(p. 70\)](#).

If you plan to offer commercial-grade services, [AWS Certificate Manager](#) is a good option.

Underlying the host certificate is the key. As of 2017, [government](#) and [industry](#) groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents through 2030. The default modulus size generated by OpenSSL in Amazon Linux is 2048 bits, which means that the existing auto-generated key is suitable for use in a CA-signed certificate. An alternative procedure is described below for those who desire a customized key, for instance, one with a larger modulus or using a different encryption algorithm.

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

To obtain a CA-signed certificate

1. [Connect to your instance \(p. 11\)](#) and navigate to `/etc/pki/tls/private/`. This is the directory where the server's private key for TLS is stored. If you prefer to use your existing host key to generate the CSR, skip to Step 3.
2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys work with your web server, but they vary in how (and how much) security they implement.
 - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key
```

- **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, **custom.key**, is a 4096-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
```

- **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, **custom.key**, is a 4096-bit RSA private key encrypted with the AES-128 cipher.

Important

Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

```
[ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out custom.key 4096
```

- **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

```
[ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
```

The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, [according to NIST](#).

Note

Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as follows:

```
[ec2-user ~]$ sudo chown root.root custom.key
[ec2-user ~]$ sudo chmod 600 custom.key
[ec2-user ~]$ ls -al custom.key
```

The commands above should yield the following result:

```
-rw----- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key; the example below uses **custom.key**:

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

Name	Description	Example
Country Name	The two-letter ISO abbreviation for your country.	US (=United States)
State or Province Name	The name of the state or province where your organization is located. This name cannot be abbreviated.	Washington
Locality Name	The location of your organization, such as a city.	Seattle
Organization Name	The full legal name of your organization. Do not abbreviate your organization name.	Example Corporation
Organizational Unit Name	Additional organizational information, if any.	Example Dept
Common Name	This value must exactly match the web address that you expect users to type into a browser. Usually, this means a domain name with a prefixed host name or alias in the form www.example.com . In testing with a self-signed certificate and no DNS resolution, the common name may consist of the host name alone. CAs also offer more expensive certificates that accept wild-card names such as *.example.com .	www.example.com
Email Address	The server administrator's email address.	someone@example.com

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file **csr.pem** contains your public key, your digital signature of your public key, and the metadata that you entered.

4. Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If **www.example.com** is the common name, then **example.com** would be a good SAN, and vice versa. A visitor to your site typing in either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA's chain of trust.

Note

Your CA may send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a **.pem** or **.crt** extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following:

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following:

```
- - - - -END CERTIFICATE - - - - -
```

You can also test a file at the command line as follows:

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with .p7b, .p7c, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the /etc/pki/tls/certs directory.

Note

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/certs directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user certs]$ sudo chown root.root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

The commands above should yield the following result:

```
-rw----- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The commands would be:

```
[ec2-user certs]$ sudo chown root.root intermediate.crt
[ec2-user certs]$ sudo chmod 644 intermediate.crt
[ec2-user certs]$ ls -al intermediate.crt
```

The commands above should yield the following result:

```
-rw-r--r-- root root intermediate.crt
```

6. If you used a custom key to create your CSR and the resulting host certificate, remove or rename the old key from the /etc/pki/tls/private/ directory, and then install the new key there.

Note

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (vi, nano, notepad, etc.) on both your local computer and your instance, and then copy and paste the file contents

between them. You need root [sudo] privileges when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/private directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only). The commands would be as follows:

```
[ec2-user private]$ sudo chown root.root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ ls -al custom.key
```

The commands above should yield the following result:

```
-rw----- root root custom.key
```

7. Edit /etc/httpd/conf.d/ssl.conf to reflect your new certificate and key files.

- a. Provide the path and file name of the CA-signed host certificate in Apache's SSLCertificateFile directive:

```
SSLCertificateFile /etc/pki/tls/certs/custom.crt
```

- b. If you received an intermediate certificate file (intermediate.crt in this example), provide its path and file name using Apache's SSLCACertificateFile directive:

```
SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
```

Note

Some CAs combine the host certificate and the intermediate certificates in a single file, making this directive unnecessary. Consult the instructions provided by your CA.

- c. Provide the path and file name of the private key in Apache's SSLCertificateKeyFile directive:

```
SSLCertificateKeyFile /etc/pki/tls/private/custom.key
```

8. Save /etc/httpd/conf.d/ssl.conf and restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
```

9. Test your server by entering your domain name into a browser URL bar with the prefix `https://`. Your browser should load the test page over HTTPS without generating errors.

Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as [Qualys SSL Labs](#), which performs a free and thorough analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see [how Qualys formulates its scores](#).

Important

Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change

constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the [Qualys SSL Labs](#) site, type the fully qualified domain name of your server, in the form `www.example.com`. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems. For example:

x The RC4 cipher is supported for use by certain older browsers. A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several [serious weaknesses](#). Unless you have very good reasons to support legacy browsers, you should disable this.

x Old TLS versions are supported. The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

To correct the TLS configuration

1. Open the configuration file `/etc/httpd/conf.d/ssl.conf` in a text editor and comment out the following lines by typing "#" at the beginning of each:

```
#SSLProtocol all -SSLv3  
#SSLProxyProtocol all -SSLv3
```

2. Add the following directives:

```
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2  
SSLProxyProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

These directives explicitly disable SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive communicates more clearly, to a human reader, what the server is configured to do.

Note

Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. Open the configuration file `/etc/httpd/conf.d/ssl.conf` and find the section with commented-out examples for configuring `SSLCipherSuite` and `SSLProxyCipherSuite`.

```
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5  
#SSLProxyCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

Leave these as they are, and below them add the following directives:

Note

Though shown here on several lines for readability, each of these two directives must be on a single line without spaces between the cipher names.

```
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-  
CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-  
SHA256:ECDHE-ECDSA-AES256-SHA384:  
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:!aNULL:  
eNULL:!EXPORT:!DES:
```

```
!RC4:!MD5:!PSK:!aECDH:!EDH-DSS-DES-CBC3-SHA:!EDH-RSA-DES-CBC3-SHA:!KRB5-DES-CBC3-SHA  
SSLProxyCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-  
ECDSA-CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-  
SHA256:ECDHE-ECDSA-AES256-SHA384:  
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:!aNULL:  
eNULL:!EXPORT:!DES:  
!RC4:!MD5:!PSK:!aECDH:!EDH-DSS-DES-CBC3-SHA:!EDH-RSA-DES-CBC3-SHA:!KRB5-DES-CBC3-SHA
```

These ciphers are a subset of the much longer list of supported ciphers in OpenSSL. They were selected and ordered according to the following criteria:

- Support for forward secrecy
- Strength
- Speed
- Specific ciphers before cipher families
- Allowed ciphers before denied ciphers

The high-ranking ciphers have *ECDHE* in their names, for *Elliptic Curve Diffie-Hellman Ephemeral*; the *ephemeral* indicates forward secrecy. Also, RC4 is now among the forbidden ciphers near the end.

We recommend that you use an explicit list of ciphers instead relying on defaults or terse directives whose content isn't visible. The cipher list shown here is just one of many possible lists; for instance, you might want to optimize a list for speed rather than forward secrecy.

If you anticipate a need to support older clients, you can allow the DES-CBC3-SHA cipher suite.

Each update to OpenSSL introduces new ciphers and deprecates old ones. Keep your EC2 Amazon Linux instance up to date, watch for security announcements from [OpenSSL](#), and be alert to reports of new security exploits in the technical press.

2. Uncomment the following line by removing the "#":

```
#SSLHonorCipherOrder on
```

This command forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strongly secure connection before falling back to allowed ciphers with lesser security.

3. Restart Apache. If you test the domain again on [Qualys SSL Labs](#), you should see that the RC4 vulnerability is gone.

Troubleshoot

- **My Apache webserver won't start unless I enter a password**

This is expected behavior if you installed an encrypted, password-protected, private server key.

You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/  
[ec2-user private]$ sudo cp custom.key custom.key.bak
```

```
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out
custom.key.nocrypt
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key
[ec2-user private]$ sudo chown root.root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ sudo service httpd restart
```

Apache should now start without prompting you for a password.

Tutorial: Host a WordPress blog on Amazon Linux 2022

The following procedures will help you install, configure, and secure a WordPress blog on your Amazon Linux 2022 instance. This tutorial is a good introduction to using Amazon EC2 in that you have full control over a web server that hosts your WordPress blog, which is not typical with a traditional hosting service.

You are responsible for updating the software packages and maintaining security patches for your server. For a more automated WordPress installation that does not require direct interaction with the web server configuration, the AWS CloudFormation service provides a WordPress template that can also get you started quickly. For more information, see [Get started](#) in the *AWS CloudFormation User Guide*. If you'd prefer to host your WordPress blog on a Windows instance, see [Deploy a WordPress blog on your Amazon EC2 Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*. If you need a high-availability solution with a decoupled database, see [Deploying a high-availability WordPress website](#) in the *AWS Elastic Beanstalk Developer Guide*.

Important

These procedures are intended for use with Amazon Linux 2022. For more information about other distributions, see their specific documentation. Many steps in this tutorial do not work on Ubuntu instances. For help installing WordPress on an Ubuntu instance, see [WordPress](#) in the Ubuntu documentation. You can also use [CodeDeploy](#) to accomplish this task on Amazon Linux, macOS, or Unix systems.

Topics

- [Prerequisites \(p. 84\)](#)
- [Install WordPress \(p. 85\)](#)
- [Next steps \(p. 91\)](#)
- [Help! My public DNS name changed and now my blog is broken \(p. 92\)](#)

Prerequisites

We strongly recommend that you associate an Elastic IP address (EIP) to the instance you are using to host a WordPress blog. This prevents the public DNS address for your instance from changing and breaking your installation. If you own a domain name and you want to use it for your blog, you can update the DNS record for the domain name to point to your EIP address (for help with this, contact your domain name registrar). You can have one EIP address associated with a running instance at no charge. For more information, see [Elastic IP addresses \(p. 1082\)](#). The [Tutorial: Install a LAMP web server on the Amazon Linux AMI \(p. 35\)](#) tutorial has steps for configuring a security group to allow HTTP and HTTPS traffic, as well as several steps to ensure that file permissions are set properly for your web server. For information about adding rules to your security group, see [Add rules to a security group \(p. 1333\)](#).

If you don't already have a domain name for your blog, you can register a domain name with Route 53 and associate your instance's EIP address with your domain name. For more information, see [Registering domain names using Amazon Route 53](#) in the *Amazon Route 53 Developer Guide*.

Install WordPress

Connect to your instance (p. 11), and download the WordPress installation package.

1. Download and install these packages using the following command.

```
dnf install wget php-mysqlnd httpd mysql php-fpm php-mysqli php-json php php-devel -y
```

2. You may notice a warning displayed with similar verbiage in the output (the versions may vary over time):

```
WARNING:  
A newer release of "Amazon Linux" is available.  
  
Available Versions:  
  
dnf update --releasever=2022.0.20220202  
  
Release notes:  
https://aws.amazon.com  
  
Version 2022.0.20220204:  
Run the following command to update to 2022.0.20220204:  
  
dnf update --releasever=2022.0.20220204 ... etc
```

As a best-practice we recommend keeping the OS as up-to-date as possible, but you may want to iterate through each version to ensure there are no conflicts in your environment. **If installation of the preceding packages noted in step 1 fail, you may need to update to one of the newer releases listed, and retry.**

3. Download the latest WordPress installation package with the **wget** command. The following command should always download the latest release.

```
[ec2-user ~]$ wget https://wordpress.org/latest.tar.gz
```

4. Unzip and unarchive the installation package. The installation folder is unzipped to a folder called **wordpress**.

```
[ec2-user ~]$ tar -xzf latest.tar.gz
```

To create a database user and database for your WordPress installation

Your WordPress installation needs to store information, such as blog posts and user comments, in a database. This procedure helps you create your blog's database and a user that is authorized to read and save information to it.

1. Start the database and web server.

```
[ec2-user ~]$ sudo systemctl start mariadb httpd
```

2. Log in to the database server as the **root** user. Enter your database **root** password when prompted; this may be different than your **root** system password, or it might even be empty if you have not secured your database server.

If you have not secured your database server yet, it is important that you do so. For more information, see [To secure the MariaDB server \(p. 30\)](#) (Amazon Linux 2022) or [To secure the database server \(p. 40\)](#) (Amazon Linux 2022 AMI).

```
[ec2-user ~]$ mysql -u root -p
```

3. Create a user and password for your MySQL database. Your WordPress installation uses these values to communicate with your MySQL database. Enter the following command, substituting a unique user name and password.

```
CREATE USER 'wordpress-user'@'localhost' IDENTIFIED BY 'your_strong_password';
```

Make sure that you create a strong password for your user. Do not use the single quote character (') in your password, because this will break the preceding command. For more information about creating a secure password, go to <http://www.pctools.com/guides/password/>. Do not reuse an existing password, and make sure to store this password in a safe place.

4. Create your database. Give your database a descriptive, meaningful name, such as `wordpress-db`.

Note

The punctuation marks surrounding the database name in the command below are called backticks. The backtick (`) key is usually located above the Tab key on a standard keyboard. Backticks are not always required, but they allow you to use otherwise illegal characters, such as hyphens, in database names.

```
CREATE DATABASE `wordpress-db`;
```

5. Grant full privileges for your database to the WordPress user that you created earlier.

```
GRANT ALL PRIVILEGES ON `wordpress-db`.* TO "wordpress-user"@"localhost";
```

6. Flush the database privileges to pick up all of your changes.

```
FLUSH PRIVILEGES;
```

7. Exit the `mysql` client.

```
exit
```

To create and edit the `wp-config.php` file

The WordPress installation folder contains a sample configuration file called `wp-config-sample.php`. In this procedure, you copy this file and edit it to fit your specific configuration.

1. Copy the `wp-config-sample.php` file to a file called `wp-config.php`. This creates a new configuration file and keeps the original sample file intact as a backup.

```
[ec2-user ~]$ cp wordpress/wp-config-sample.php wordpress/wp-config.php
```

2. Edit the `wp-config.php` file with your favorite text editor (such as `nano` or `vim`) and enter values for your installation. If you do not have a favorite text editor, `nano` is suitable for beginners.

```
[ec2-user ~]$ nano wordpress/wp-config.php
```

- a. Find the line that defines DB_NAME and change database_name_here to the database name that you created in [Step 4 \(p. 86\) of To create a database user and database for your WordPress installation \(p. 85\)](#).

```
define('DB_NAME', 'wordpress-db');
```

- b. Find the line that defines DB_USER and change username_here to the database user that you created in [Step 3 \(p. 86\) of To create a database user and database for your WordPress installation \(p. 85\)](#).

```
define('DB_USER', 'wordpress-user');
```

- c. Find the line that defines DB_PASSWORD and change password_here to the strong password that you created in [Step 3 \(p. 86\) of To create a database user and database for your WordPress installation \(p. 85\)](#).

```
define('DB_PASSWORD', 'your_strong_password');
```

- d. Find the section called Authentication Unique Keys and Salts. These KEY and SALT values provide a layer of encryption to the browser cookies that WordPress users store on their local machines. Basically, adding long, random values here makes your site more secure. Visit <https://api.wordpress.org/secret-key/1.1/salt/> to randomly generate a set of key values that you can copy and paste into your wp-config.php file. To paste text into a PuTTY terminal, place the cursor where you want to paste the text and right-click your mouse inside the PuTTY terminal.

For more information about security keys, go to <https://wordpress.org/support/article/editing-wp-config-php/#security-keys>.

Note

The values below are for example purposes only; do not use these values for your installation.

```
define('AUTH_KEY', '#U$$+[RXN8:b^-L_0(WU_+ c+WfkI~c]o]-bHw+)/Aj[wTwSiz<Qb[mghExcRh-');  
define('SECURE_AUTH_KEY', 'zsz._P=l/|y.Lq)Xjlkws1y5NJ76E6EJ.AV0pCKZZB,*-*r ?6OP  
$eJ@;+(ndLg');  
define('LOGGED_IN_KEY', 'ju}qwre3V*+8f_zOWF?{LlGsQ]Ye@2Jh^,8x>)Y |;(^[Iw]Pi  
+LG#A4R?7N`YB3');  
define('NONCE_KEY', 'P(g62HeZxEes/LnI^i=H,[XwK9I&[2s|:?ON}VJM%?;v2v)v+;  
+^9eXUahg@::Cj');  
define('AUTH_SALT', 'C$DpB4Hj[JK:{ql`sRVA:{:7yShy(9A@5wg+`JJVb1fk%_-  
Bx*M4(qc[Og%JT!h');  
define('SECURE_AUTH_SALT', 'd!uRu#)+q#{f$Z?Z9uFPG.${+S{n~1M&%@~gL>U>NV<zpD-@2-  
Es7Q1O-bp28EKv');  
define('LOGGED_IN_SALT', 'j{00P*owZf)kVD+FVLn-->. |Y%Ug4#I^*LVd9QeZ^&XmK/e(76mic  
+&W+^OP');  
define('NONCE_SALT', '-97r*V/cgxLmp?Zy4zUU4r99QQ_xGs2LTd%P; |  
_eits)8_B/, .6[=UK<J_y9?JWG');
```

- e. Save the file and exit your text editor.

To install your WordPress files under the Apache document root

- Now that you've unzipped the installation folder, created a MySQL database and user, and customized the WordPress configuration file, you are ready to copy your installation files to your web server document root so you can run the installation script that completes your installation. The location of these files depends on whether you want your WordPress blog to be available

at the actual root of your web server (for example, my.public.dns.amazonaws.com) or in a subdirectory or folder under the root (for example, my.public.dns.amazonaws.com/blog).

- If you want WordPress to run at your document root, copy the contents of the wordpress installation directory (but not the directory itself) as follows:

```
[ec2-user ~]$ cp -r wordpress/* /var/www/html/
```

- If you want WordPress to run in an alternative directory under the document root, first create that directory, and then copy the files to it. In this example, WordPress will run from the directory blog:

```
[ec2-user ~]$ mkdir /var/www/html/blog
[ec2-user ~]$ cp -r wordpress/* /var/www/html/blog/
```

Important

For security purposes, if you are not moving on to the next procedure immediately, stop the Apache web server (`httpd`) now. After you move your installation under the Apache document root, the WordPress installation script is unprotected and an attacker could gain access to your blog if the Apache web server were running. To stop the Apache web server, enter the command **sudo service httpd stop**. If you are moving on to the next procedure, you do not need to stop the Apache web server.

To allow WordPress to use permalinks

WordPress permalinks need to use Apache .htaccess files to work properly, but this is not enabled by default on Amazon Linux. Use this procedure to allow all overrides in the Apache document root.

1. Open the `httpd.conf` file with your favorite text editor (such as **nano** or **vim**). If you do not have a favorite text editor, **nano** is suitable for beginners.

```
[ec2-user ~]$ sudo vim /etc/httpd/conf/httpd.conf
```

2. Find the section that starts with `<Directory "/var/www/html">`.

```
<Directory "/var/www/html">
#
# Possible values for the Options directive are "None", "All",
# or any combination of:
#   Indexes Includes FollowSymLinks SymLinksifOwnerMatch ExecCGI MultiViews
#
# Note that "MultiViews" must be named *explicitly* --- "Options All"
# doesn't give it to you.
#
# The Options directive is both complicated and important. Please see
# http://httpd.apache.org/docs/2.4/mod/core.html#options
# for more information.
#
Options Indexes FollowSymLinks

#
# AllowOverride controls what directives may be placed in .htaccess files.
# It can be "All", "None", or any combination of the keywords:
#   Options FileInfo AuthConfig Limit
#
AllowOverride None

#
# Controls who can get stuff from this server.
#
```

```
Require all granted
</Directory>
```

3. Change the AllowOverride None line in the above section to read AllowOverride **All**.

Note

There are multiple AllowOverride lines in this file; be sure you change the line in the <Directory "/var/www/html"> section.

```
AllowOverride All
```

4. Save the file and exit your text editor.

To install the PHP graphics drawing library on Amazon Linux 2022

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

Use the following command to install the PHP graphics drawing library on Amazon Linux 2022. For example, if you installed php7.2 from amazon-linux-extras as part of installing the LAMP stack, this command installs version 7.2 of the PHP graphics drawing library.

```
[ec2-user ~]$ sudo dnf install php-gd
```

To verify the installed version, use the following command:

```
[ec2-user ~]$ sudo dnf list installed | grep php-gd
```

The following is example output:

php-gd.x86_64	7.2.30-1.amzn2	@amzn2extra-php7.2
---------------	----------------	--------------------

To install the PHP graphics drawing library on the Amazon Linux AMI

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

To verify which versions are available, use the following command:

```
[ec2-user ~]$ dnf list | grep php-gd
```

The following is an example line from the output for the PHP graphics drawing library (version 7.2):

php72-gd.x86_64	7.2.30-1.22.amzn1	amzn-updates
-----------------	-------------------	--------------

Use the following command to install a specific version of the PHP graphics drawing library (for example, version 7.2) on the Amazon Linux AMI:

```
[ec2-user ~]$ sudo dnf install php72-gd
```

To fix file permissions for the Apache web server

Some of the available features in WordPress require write access to the Apache document root (such as uploading media through the Administration screens). If you have not already done so, apply the

following group memberships and permissions (as described in greater detail in the [LAMP web server tutorial \(p. 35\)](#)).

1. Grant file ownership of /var/www and its contents to the apache user.

```
[ec2-user ~]$ sudo chown -R apache /var/www
```

2. Grant group ownership of /var/www and its contents to the apache group.

```
[ec2-user ~]$ sudo chgrp -R apache /var/www
```

3. Change the directory permissions of /var/www and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www  
[ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} \;
```

4. Recursively change the file permissions of /var/www and its subdirectories to add group write permissions.

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

5. Restart the Apache web server to pick up the new group and permissions.

- Amazon Linux 2022

```
[ec2-user ~]$ sudo systemctl restart httpd
```

•

To run the WordPress installation script with Amazon Linux 2022

You are ready to install WordPress. The commands that you use depend on the operating system. The commands in this procedure are for use with Amazon Linux 2022. Use the procedure that follows this one with Amazon Linux 2022 AMI.

1. Use the **systemctl** command to ensure that the httpd and database services start at every system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd && sudo systemctl enable mariadb
```

2. Verify that the database server is running.

```
[ec2-user ~]$ sudo systemctl status mariadb
```

If the database service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

3. Verify that your Apache web server (httpd) is running.

```
[ec2-user ~]$ sudo systemctl status httpd
```

If the httpd service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start httpd
```

4. In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose **Install WordPress** to complete the installation. For more information, see [Step 5: Run the Install Script](#) on the WordPress website.

To run the WordPress installation script with Amazon Linux 2022 AMI

1. Use the **chkconfig** command to ensure that the **httpd** and database services start at every system boot.

```
[ec2-user ~]$ sudo chkconfig httpd on && sudo chkconfig mysqld on
```

2. Verify that the database server is running.

```
[ec2-user ~]$ sudo service mysqld status
```

If the database service is not running, start it.

```
[ec2-user ~]$ sudo service mysqld start
```

3. Verify that your Apache web server (**httpd**) is running.

```
[ec2-user ~]$ sudo service httpd status
```

If the **httpd** service is not running, start it.

```
[ec2-user ~]$ sudo service httpd start
```

4. In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose **Install WordPress** to complete the installation. For more information, see [Step 5: Run the Install Script](#) on the WordPress website.

Next steps

After you have tested your WordPress blog, consider updating its configuration.

Use a custom domain name

If you have a domain name associated with your EC2 instance's EIP address, you can configure your blog to use that name instead of the EC2 public DNS address. For more information, see [Changing The Site URL](#) on the WordPress website.

Configure your blog

You can configure your blog to use different [themes](#) and [plugins](#) to offer a more personalized experience for your readers. However, sometimes the installation process can backfire, causing you to lose your entire blog. We strongly recommend that you create a backup Amazon Machine Image (AMI) of your instance before attempting to install any themes or plugins so you can restore your blog if anything goes wrong during installation. For more information, see [Create your own AMI \(p. 104\)](#).

Increase capacity

If your WordPress blog becomes popular and you need more compute power or storage, consider the following steps:

- Expand the storage space on your instance. For more information, see [Amazon EBS Elastic Volumes \(p. 1529\)](#).
- Move your MySQL database to [Amazon RDS](#) to take advantage of the service's ability to scale easily.

Improve network performance of your internet traffic

If you expect your blog to drive traffic from users located around the world, consider [AWS Global Accelerator](#). Global Accelerator helps you achieve lower latency by improving internet traffic performance between your users' client devices and your WordPress application running on AWS. Global Accelerator uses the [AWS global network](#) to direct traffic to a healthy application endpoint in the AWS Region that is closest to the client.

Help! My public DNS name changed and now my blog is broken

Your WordPress installation is automatically configured using the public DNS address for your EC2 instance. If you stop and restart the instance, the public DNS address changes (unless it is associated with an Elastic IP address) and your blog will not work anymore because it references resources at an address that no longer exists (or is assigned to another EC2 instance). A more detailed description of the problem and several possible solutions are outlined in <https://wordpress.org/support/article/changing-the-site-url/>.

If this has happened to your WordPress installation, you may be able to recover your blog with the procedure below, which uses the `wp-cli` command line interface for WordPress.

To change your WordPress site URL with the wp-cli

1. Connect to your EC2 instance with SSH.
2. Note the old site URL and the new site URL for your instance. The old site URL is likely the public DNS name for your EC2 instance when you installed WordPress. The new site URL is the current public DNS name for your EC2 instance. If you are not sure of your old site URL, you can use `curl` to find it with the following command.

```
[ec2-user ~]$ curl localhost | grep wp-content
```

You should see references to your old public DNS name in the output, which will look like this (old site URL in red):

```
<script type='text/javascript' src='http://ec2-52-8-139-223.us-west-1.compute.amazonaws.com/wp-content/themes/twentyfifteen/js/functions.js?ver=20150330'></script>
```

3. Download the `wp-cli` with the following command.

```
[ec2-user ~]$ curl -O https://raw.githubusercontent.com/wp-cli/builds/gh-pages/phar/wp-cli.phar
```

4. Search and replace the old site URL in your WordPress installation with the following command. Substitute the old and new site URLs for your EC2 instance and the path to your WordPress installation (usually /var/www/html or /var/www/html/blog).

```
[ec2-user ~]$ php wp-cli.phar search-replace 'old_site_url' 'new_site_url' --path=/path/to/wordpress/installation --skip-columns=guid
```

5. In a web browser, enter the new site URL of your WordPress blog to verify that the site is working properly again. If it is not, see <https://wordpress.org/support/article/changing-the-site-url/> and <https://wordpress.org/support/article/how-to-install-wordpress/#common-installation-problems> for more information.

Tutorial: Host a WordPress blog on Amazon Linux 2

The following procedures will help you install, configure, and secure a WordPress blog on your Amazon Linux instance. This tutorial is a good introduction to using Amazon EC2 in that you have full control over a web server that hosts your WordPress blog, which is not typical with a traditional hosting service.

You are responsible for updating the software packages and maintaining security patches for your server. For a more automated WordPress installation that does not require direct interaction with the web server configuration, the AWS CloudFormation service provides a WordPress template that can also get you started quickly. For more information, see [Get started](#) in the *AWS CloudFormation User Guide*. If you'd prefer to host your WordPress blog on a Windows instance, see [Deploy a WordPress blog on your Amazon EC2 Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*. If you need a high-availability solution with a decoupled database, see [Deploying a high-availability WordPress website](#) in the *AWS Elastic Beanstalk Developer Guide*.

Important

These procedures are intended for use with Amazon Linux. For more information about other distributions, see their specific documentation. Many steps in this tutorial do not work on Ubuntu instances. For help installing WordPress on an Ubuntu instance, see [WordPress](#) in the Ubuntu documentation. You can also use [CodeDeploy](#) to accomplish this task on Amazon Linux, macOS, or Unix systems.

Topics

- [Prerequisites \(p. 93\)](#)
- [Install WordPress \(p. 94\)](#)
- [Next steps \(p. 100\)](#)
- [Help! My public DNS name changed and now my blog is broken \(p. 101\)](#)

Prerequisites

This tutorial assumes that you have launched an Amazon Linux instance with a functional web server with PHP and database (either MySQL or MariaDB) support by following all of the steps in [Tutorial: Install a LAMP web server on the Amazon Linux AMI \(p. 35\)](#) for Amazon Linux AMI or [Tutorial: Install a LAMP web server on Amazon Linux 2 \(p. 25\)](#) for Amazon Linux 2. This tutorial also has steps for

configuring a security group to allow HTTP and HTTPS traffic, as well as several steps to ensure that file permissions are set properly for your web server. For information about adding rules to your security group, see [Add rules to a security group \(p. 1333\)](#).

We strongly recommend that you associate an Elastic IP address (EIP) to the instance you are using to host a WordPress blog. This prevents the public DNS address for your instance from changing and breaking your installation. If you own a domain name and you want to use it for your blog, you can update the DNS record for the domain name to point to your EIP address (for help with this, contact your domain name registrar). You can have one EIP address associated with a running instance at no charge. For more information, see [Elastic IP addresses \(p. 1082\)](#).

If you don't already have a domain name for your blog, you can register a domain name with Route 53 and associate your instance's EIP address with your domain name. For more information, see [Registering domain names using Amazon Route 53](#) in the *Amazon Route 53 Developer Guide*.

Install WordPress

Connect to your instance, and download the WordPress installation package.

To download and unzip the WordPress installation package

1. Download the latest WordPress installation package with the `wget` command. The following command should always download the latest release.

```
[ec2-user ~]$ wget https://wordpress.org/latest.tar.gz
```

2. Unzip and unarchive the installation package. The installation folder is unzipped to a folder called `wordpress`.

```
[ec2-user ~]$ tar -xzf latest.tar.gz
```

To create a database user and database for your WordPress installation

Your WordPress installation needs to store information, such as blog posts and user comments, in a database. This procedure helps you create your blog's database and a user that is authorized to read and save information to it.

1. Start the database server.

- Amazon Linux 2

```
[ec2-user ~]$ sudo systemctl start mariadb
```

- Amazon Linux AMI

```
[ec2-user ~]$ sudo service mysqld start
```

2. Log in to the database server as the `root` user. Enter your database `root` password when prompted; this may be different than your `root` system password, or it might even be empty if you have not secured your database server.

If you have not secured your database server yet, it is important that you do so. For more information, see [To secure the MariaDB server \(p. 30\)](#) (Amazon Linux 2) or [To secure the database server \(p. 40\)](#) (Amazon Linux AMI).

```
[ec2-user ~]$ mysql -u root -p
```

3. Create a user and password for your MySQL database. Your WordPress installation uses these values to communicate with your MySQL database. Enter the following command, substituting a unique user name and password.

```
CREATE USER 'wordpress-user'@'localhost' IDENTIFIED BY 'your_strong_password';
```

Make sure that you create a strong password for your user. Do not use the single quote character (') in your password, because this will break the preceding command. For more information about creating a secure password, go to <http://www.pctools.com/guides/password/>. Do not reuse an existing password, and make sure to store this password in a safe place.

4. Create your database. Give your database a descriptive, meaningful name, such as `wordpress-db`.

Note

The punctuation marks surrounding the database name in the command below are called backticks. The backtick (`) key is usually located above the Tab key on a standard keyboard. Backticks are not always required, but they allow you to use otherwise illegal characters, such as hyphens, in database names.

```
CREATE DATABASE `wordpress-db`;
```

5. Grant full privileges for your database to the WordPress user that you created earlier.

```
GRANT ALL PRIVILEGES ON `wordpress-db`.* TO "wordpress-user"@"localhost";
```

6. Flush the database privileges to pick up all of your changes.

```
FLUSH PRIVILEGES;
```

7. Exit the `mysql` client.

```
exit
```

To create and edit the `wp-config.php` file

The WordPress installation folder contains a sample configuration file called `wp-config-sample.php`. In this procedure, you copy this file and edit it to fit your specific configuration.

1. Copy the `wp-config-sample.php` file to a file called `wp-config.php`. This creates a new configuration file and keeps the original sample file intact as a backup.

```
[ec2-user ~]$ cp wordpress/wp-config-sample.php wordpress/wp-config.php
```

2. Edit the `wp-config.php` file with your favorite text editor (such as **nano** or **vim**) and enter values for your installation. If you do not have a favorite text editor, **nano** is suitable for beginners.

```
[ec2-user ~]$ nano wordpress/wp-config.php
```

- a. Find the line that defines `DB_NAME` and change `database_name_here` to the database name that you created in [Step 4 \(p. 95\)](#) of [To create a database user and database for your WordPress installation \(p. 94\)](#).

```
define('DB_NAME', 'wordpress-db');
```

- b. Find the line that defines DB_USER and change username_here to the database user that you created in [Step 3 \(p. 95\)](#) of [To create a database user and database for your WordPress installation \(p. 94\)](#).

```
define('DB_USER', 'wordpress-user');
```

- c. Find the line that defines DB_PASSWORD and change password_here to the strong password that you created in [Step 3 \(p. 95\)](#) of [To create a database user and database for your WordPress installation \(p. 94\)](#).

```
define('DB_PASSWORD', 'your_strong_password');
```

- d. Find the section called Authentication Unique Keys and Salts. These KEY and SALT values provide a layer of encryption to the browser cookies that WordPress users store on their local machines. Basically, adding long, random values here makes your site more secure. Visit <https://api.wordpress.org/secret-key/1.1/salt/> to randomly generate a set of key values that you can copy and paste into your wp-config.php file. To paste text into a PuTTY terminal, place the cursor where you want to paste the text and right-click your mouse inside the PuTTY terminal.

For more information about security keys, go to <https://wordpress.org/support/article/editing-wp-config-php/#security-keys>.

Note

The values below are for example purposes only; do not use these values for your installation.

```
define('AUTH_KEY', ' #U$$+[RXN8:b^-L_0(WU_+ c+WFkI-c]o]-bHw+/'
Aj[wTwSiz<Qb[mghEXcRh-');
define('SECURE_AUTH_KEY', 'Zsz._P=l/|y.Lq)Xjlkws1y5NJ76E6EJ.AV0pCKZZB,*~*r ?6OP
$eJT@;+(ndLg');
define('LOGGED_IN_KEY', 'ju}qwre3V*+8f_zOWf?{LlGsQ}Ye@2Jh^,8x>)Y |;(^[Iw]Pi

define('NONCE_KEY', 'P(g62HeZxEes/LnI^i=H,[XwK9I&[2s|:?ON}VJM%?;v2V]v+;

define('AUTH_SALT', 'C$DpB4Hj[JK:{ql`sRVa:{:7yShy(9A@5wg+`JJVb1fk%_-_

define('SECURE_AUTH_SALT', 'd!uRu#)+q#{f$Z?Z9uFPG.${+S{n~1M&%@~gL>U>NV<zpD-@2-

define('LOGGED_IN_SALT', 'j{00P*owZf)kVD+FViLn-->. |Y%Ug4#I^*Lvd9QeZ^&XmK/e(76mic

define('NONCE_SALT', '-97r*V/cgxLmp?Zy4zUU4r99QO_rGs2LTd%P;/
_e1tS)8_B/, .6[=UK<J_y9?JWG');
```

- e. Save the file and exit your text editor.

To install your WordPress files under the Apache document root

- Now that you've unzipped the installation folder, created a MySQL database and user, and customized the WordPress configuration file, you are ready to copy your installation files to your web server document root so you can run the installation script that completes your installation. The location of these files depends on whether you want your WordPress blog to be available at the actual root of your web server (for example, my.public.dns.amazonaws.com) or in a subdirectory or folder under the root (for example, my.public.dns.amazonaws.com/blog).
 - If you want WordPress to run at your document root, copy the contents of the wordpress installation directory (but not the directory itself) as follows:

```
[ec2-user ~]$ cp -r wordpress/* /var/www/html/
```

- If you want WordPress to run in an alternative directory under the document root, first create that directory, and then copy the files to it. In this example, WordPress will run from the directory blog:

```
[ec2-user ~]$ mkdir /var/www/html/blog
[ec2-user ~]$ cp -r wordpress/* /var/www/html/blog/
```

Important

For security purposes, if you are not moving on to the next procedure immediately, stop the Apache web server (`httpd`) now. After you move your installation under the Apache document root, the WordPress installation script is unprotected and an attacker could gain access to your blog if the Apache web server were running. To stop the Apache web server, enter the command `sudo service httpd stop`. If you are moving on to the next procedure, you do not need to stop the Apache web server.

To allow WordPress to use permalinks

WordPress permalinks need to use Apache `.htaccess` files to work properly, but this is not enabled by default on Amazon Linux. Use this procedure to allow all overrides in the Apache document root.

1. Open the `httpd.conf` file with your favorite text editor (such as `nano` or `vim`). If you do not have a favorite text editor, `nano` is suitable for beginners.

```
[ec2-user ~]$ sudo vim /etc/httpd/conf/httpd.conf
```

2. Find the section that starts with `<Directory "/var/www/html">`.

```
<Directory "/var/www/html">
#
# Possible values for the Options directive are "None", "All",
# or any combination of:
#   Indexes Includes FollowSymLinks SymLinksIfOwnerMatch ExecCGI MultiViews
#
# Note that "MultiViews" must be named *explicitly* --- "Options All"
# doesn't give it to you.
#
# The Options directive is both complicated and important. Please see
# http://httpd.apache.org/docs/2.4/mod/core.html#options
# for more information.
#
Options Indexes FollowSymLinks

#
# AllowOverride controls what directives may be placed in .htaccess files.
# It can be "All", "None", or any combination of the keywords:
#   Options FileInfo AuthConfig Limit
#
AllowOverride None

#
# Controls who can get stuff from this server.
#
Require all granted
</Directory>
```

3. Change the `AllowOverride None` line in the above section to read `AllowOverride All`.

Note

There are multiple `AllowOverride` lines in this file; be sure you change the line in the `<Directory "/var/www/html">` section.

```
AllowOverride All
```

4. Save the file and exit your text editor.

To install the PHP graphics drawing library on Amazon Linux 2

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

Use the following command to install the PHP graphics drawing library on Amazon Linux 2. For example, if you installed php7.2 from amazon-linux-extras as part of installing the LAMP stack, this command installs version 7.2 of the PHP graphics drawing library.

```
[ec2-user ~]$ sudo yum install php-gd
```

To verify the installed version, use the following command:

```
[ec2-user ~]$ sudo yum list installed | grep php-gd
```

The following is example output:

php-gd.x86_64	7.2.30-1.amzn2	@amzn2extra-php7.2
---------------	----------------	--------------------

To install the PHP graphics drawing library on the Amazon Linux AMI

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

To verify which versions are available, use the following command:

```
[ec2-user ~]$ yum list | grep php-gd
```

The following is an example line from the output for the PHP graphics drawing library (version 7.2):

php72-gd.x86_64	7.2.30-1.22.amzn1	amzn-updates
-----------------	-------------------	--------------

Use the following command to install a specific version of the PHP graphics drawing library (for example, version 7.2) on the Amazon Linux AMI:

```
[ec2-user ~]$ sudo yum install php72-gd
```

To fix file permissions for the Apache web server

Some of the available features in WordPress require write access to the Apache document root (such as uploading media through the Administration screens). If you have not already done so, apply the following group memberships and permissions (as described in greater detail in the [LAMP web server tutorial \(p. 35\)](#)).

1. Grant file ownership of /var/www and its contents to the apache user.

```
[ec2-user ~]$ sudo chown -R apache /var/www
```

2. Grant group ownership of /var/www and its contents to the apache group.

```
[ec2-user ~]$ sudo chgrp -R apache /var/www
```

3. Change the directory permissions of /var/www and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www
[ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} \;
```

4. Recursively change the file permissions of /var/www and its subdirectories to add group write permissions.

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

5. Restart the Apache web server to pick up the new group and permissions.

- Amazon Linux 2

```
[ec2-user ~]$ sudo systemctl restart httpd
```

- Amazon Linux AMI

```
[ec2-user ~]$ sudo service httpd restart
```

To run the WordPress installation script with Amazon Linux 2

You are ready to install WordPress. The commands that you use depend on the operating system. The commands in this procedure are for use with Amazon Linux 2. Use the procedure that follows this one with Amazon Linux AMI.

1. Use the **systemctl** command to ensure that the **httpd** and database services start at every system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd && sudo systemctl enable mariadb
```

2. Verify that the database server is running.

```
[ec2-user ~]$ sudo systemctl status mariadb
```

If the database service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

3. Verify that your Apache web server (**httpd**) is running.

```
[ec2-user ~]$ sudo systemctl status httpd
```

If the **httpd** service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start httpd
```

4. In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose **Install WordPress** to

complete the installation. For more information, see [Step 5: Run the Install Script](#) on the WordPress website.

To run the WordPress installation script with Amazon Linux AMI

1. Use the `chkconfig` command to ensure that the `httpd` and database services start at every system boot.

```
[ec2-user ~]$ sudo chkconfig httpd on && sudo chkconfig mysqld on
```

2. Verify that the database server is running.

```
[ec2-user ~]$ sudo service mysqld status
```

If the database service is not running, start it.

```
[ec2-user ~]$ sudo service mysqld start
```

3. Verify that your Apache web server (`httpd`) is running.

```
[ec2-user ~]$ sudo service httpd status
```

If the `httpd` service is not running, start it.

```
[ec2-user ~]$ sudo service httpd start

Amazon Machine Images (AMI)

An Amazon Machine Image (AMI) provides the information required to launch an instance. You must specify an AMI when you launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. You can use different AMIs to launch instances when you need instances with different configurations.

An AMI includes the following:

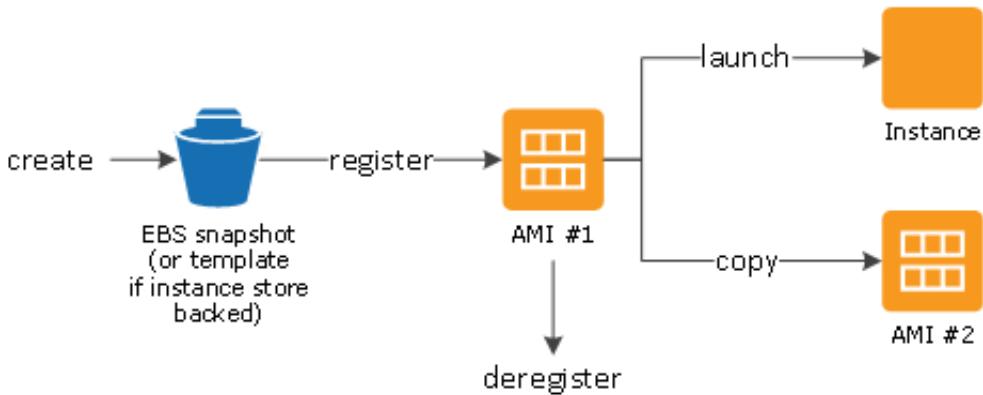

- One or more Amazon Elastic Block Store (Amazon EBS) snapshots, or, for instance-store-backed AMIs, a template for the root volume of the instance (for example, an operating system, an application server, and applications).
- Launch permissions that control which AWS accounts can use the AMI to launch instances.
- A block device mapping that specifies the volumes to attach to the instance when it's launched.

Use an AMI

The following diagram summarizes the AMI lifecycle. After you create and register an AMI, you can use it to launch new instances. (You can also launch instances from an AMI if the AMI owner grants you launch permissions.) You can copy an AMI within the same AWS Region or to different AWS Regions. When you no longer require an AMI, you can deregister it.

You can search for an AMI that meets the criteria for your instance. You can search for AMIs provided by AWS or AMIs provided by the community. For more information, see [AMI types \(p. 105\)](#) and [Find a Linux AMI \(p. 117\)](#).

After you launch an instance from an AMI, you can connect to it. When you are connected to an instance, you can use it just like you use any other server. For information about launching, connecting, and using your instance, see [Tutorial: Get started with Amazon EC2 Linux instances \(p. 9\)](#).

Create your own AMI

You can launch an instance from an existing AMI, customize the instance (for example, [install software \(p. 674\)](#) on the instance), and then save this updated configuration as a custom AMI. Instances launched from this new custom AMI include the customizations that you made when you created the AMI.

The root storage device of the instance determines the process you follow to create an AMI. The root volume of an instance is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information about the root device volume, see [Amazon EC2 instance root device volume \(p. 1645\)](#).

- To create an Amazon EBS-backed AMI, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#).
- To create an instance store-backed AMI, see [Create an instance store-backed Linux AMI \(p. 149\)](#).

To help categorize and manage your AMIs, you can assign custom *tags* to them. For more information, see [Tag your Amazon EC2 resources \(p. 1692\)](#).

Buy, share, and sell AMIs

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see [Shared AMIs \(p. 122\)](#).

You can purchase AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users. For more information about buying or selling AMIs, see [Paid AMIs \(p. 140\)](#).

Deregister your AMI

You can deregister an AMI when you have finished with it. After you deregister an AMI, it can't be used to launch new instances. Existing instances launched from the AMI are not affected. For more information, see [Deregister your Linux AMI \(p. 196\)](#).

Amazon Linux 2 and Amazon Linux AMI

Amazon Linux 2 and the Amazon Linux AMI are supported and maintained Linux images provided by AWS. The following are some of the features of Amazon Linux 2 and Amazon Linux AMI:

- A stable, secure, and high-performance execution environment for applications running on Amazon EC2.
- Provided at no additional charge to Amazon EC2 users.
- Repository access to multiple versions of MySQL, PostgreSQL, Python, Ruby, Tomcat, and many more common packages.
- Updated on a regular basis to include the latest components, and these updates are also made available in the **yum** repositories for installation on running instances.
- Includes packages that enable easy integration with AWS services, such as the AWS CLI, Amazon EC2 API and AMI tools, the Boto library for Python, and the Elastic Load Balancing tools.

For more information, see [Amazon Linux \(p. 211\)](#).

AMI types

You can select an AMI to use based on the following characteristics:

- Region (see [Regions and Zones \(p. 1022\)](#))
- Operating system
- Architecture (32-bit or 64-bit)
- [Launch permissions \(p. 105\)](#)
- Storage for the root device (p. 106)

Launch permissions

The owner of an AMI determines its availability by specifying launch permissions. Launch permissions fall into the following categories.

Launch permission	Description
public	The owner grants launch permissions to all AWS accounts.
explicit	The owner grants launch permissions to specific AWS accounts, organizations, or organizational units (OUs).
implicit	The owner has implicit launch permissions for an AMI.

Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see [Shared AMIs \(p. 122\)](#). Developers can charge for their AMIs. For more information, see [Paid AMIs \(p. 140\)](#).

Storage for the root device

All AMIs are categorized as either *backed by Amazon EBS* or *backed by instance store*.

- Amazon EBS-backed AMI – The root device for an instance launched from the AMI is an Amazon Elastic Block Store (Amazon EBS) volume created from an Amazon EBS snapshot.
- Amazon instance store-backed AMI – The root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

For more information, see [Amazon EC2 instance root device volume \(p. 1645\)](#).

The following table summarizes the important differences when using the two types of AMIs.

Characteristic	Amazon EBS-backed AMI	Amazon instance store-backed AMI
Boot time for an instance	Usually less than 1 minute	Usually less than 5 minutes
Size limit for a root device	64 TiB**	10 GiB
Root device volume	EBS volume	Instance store volume
Data persistence	By default, the root volume is deleted when the instance terminates.* Data on any other EBS volumes persists after instance termination by default.	Data on any instance store volumes persists only during the life of the instance.
Modifications	The instance type, kernel, RAM disk, and user data can be changed while the instance is stopped.	Instance attributes are fixed for the life of an instance.
Charges	You're charged for instance usage, EBS volume usage, and storing your AMI as an EBS snapshot.	You're charged for instance usage and storing your AMI in Amazon S3.
AMI creation/bundling	Uses a single command/call	Requires installation and use of AMI tools
Stopped state	Can be in a stopped state. Even when the instance is stopped and not running, the root volume is persisted in Amazon EBS	Cannot be in a stopped state; instances are running or terminated

* By default, EBS root volumes have the `DeleteOnTermination` flag set to `true`. For information about how to change this flag so that the volume persists after termination, see [Change the root volume to persist \(p. 1649\)](#).

** Supported with io2 EBS Block Express only. For more information, see [io2 Block Express volumes \(p. 1359\)](#).

Determine the root device type of your AMI

New console

To determine the root device type of an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and select the AMI.
3. On the **Details** tab, check the value of **Root device type** as follows:
 - `ebs` – This is an EBS-backed AMI.
 - `instance store` – This is an instance store-backed AMI.

Old console

To determine the root device type of an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and select the AMI.
3. On the **Details** tab, check the value of **Root Device Type** as follows:
 - `ebs` – This is an EBS-backed AMI.
 - `instance store` – This is an instance store-backed AMI.

To determine the root device type of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [describe-images \(AWS CLI\)](#)
- [Get-EC2Image \(AWS Tools for Windows PowerShell\)](#)

Stopped state

You can stop an instance that has an EBS volume for its root device, but you can't stop an instance that has an instance store volume for its root device.

Stopping causes the instance to stop running (its status goes from `running` to `stopping` to `stopped`). A stopped instance persists in Amazon EBS, which allows it to be restarted. Stopping is different from terminating; you can't restart a terminated instance. Because instances with an instance store volume for the root device can't be stopped, they're either running or terminated. For more information about what happens and what you can do while an instance is stopped, see [Stop and start your instance \(p. 637\)](#).

Default data storage and persistence

Instances that have an instance store volume for the root device automatically have instance store available (the root volume contains the root partition and you can store additional data). You can add persistent storage to your instance by attaching one or more EBS volumes. Any data on an instance store volume is deleted when the instance fails or terminates. For more information, see [Instance store lifetime \(p. 1621\)](#).

Instances that have Amazon EBS for the root device automatically have an EBS volume attached. The volume appears in your list of volumes like any other. With most instance types, instances that have an EBS volume for the root device don't have instance store volumes by default. You can add instance

store volumes or additional EBS volumes using a block device mapping. For more information, see [Block device mappings \(p. 1654\)](#).

Boot times

Instances launched from an Amazon EBS-backed AMI launch faster than instances launched from an instance store-backed AMI. When you launch an instance from an instance store-backed AMI, all the parts have to be retrieved from Amazon S3 before the instance is available. With an Amazon EBS-backed AMI, only the parts required to boot the instance need to be retrieved from the snapshot before the instance is available. However, the performance of an instance that uses an EBS volume for its root device is slower for a short time while the remaining parts are retrieved from the snapshot and loaded into the volume. When you stop and restart the instance, it launches quickly, because the state is stored in an EBS volume.

AMI creation

To create Linux AMIs backed by instance store, you must create an AMI from your instance on the instance itself using the Amazon EC2 AMI tools.

AMI creation is much easier for AMIs backed by Amazon EBS. The `CreateImage` API action creates your Amazon EBS-backed AMI and registers it. There's also a button in the AWS Management Console that lets you create an AMI from a running instance. For more information, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#).

How you're charged

With AMIs backed by instance store, you're charged for instance usage and storing your AMI in Amazon S3. With AMIs backed by Amazon EBS, you're charged for instance usage, EBS volume storage and usage, and storing your AMI as an EBS snapshot.

With Amazon EC2 instance store-backed AMIs, each time you customize an AMI and create a new one, all of the parts are stored in Amazon S3 for each AMI. So, the storage footprint for each customized AMI is the full size of the AMI. For Amazon EBS-backed AMIs, each time you customize an AMI and create a new one, only the changes are stored. So, the storage footprint for subsequent AMIs that you customize after the first is much smaller, resulting in lower AMI storage charges.

When an instance with an EBS volume for its root device is stopped, you're not charged for instance usage; however, you're still charged for volume storage. As soon as you start your instance, we charge a minimum of one minute for usage. After one minute, we charge only for the seconds used. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage. We charge you for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

Linux AMI virtualization types

Linux Amazon Machine Images use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance.

For the best performance, we recommend that you use current generation instance types and HVM AMIs when you launch your instances. For more information about current generation instance types, see [Amazon EC2 Instance Types](#). If you are using previous generation instance types and would like to upgrade, see [Upgrade Paths](#).

The following table compares HVM and PV AMIs.

	HVM	PV
Description	HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest.	PV AMIs boot with a special boot loader called PV-GRUB, which starts the boot cycle and then chain loads the kernel specified in the <code>menu.1st</code> file on your image. Paravirtual guests can run on host hardware that does not have explicit support for virtualization. Historically, PV guests had better performance than HVM guests in many cases, but because of enhancements in HVM virtualization and the availability of PV drivers for HVM AMIs, this is no longer true. For more information about PV-GRUB and its use in Amazon EC2, see User provided kernels (p. 229) .
Support for hardware extensions	Yes. Unlike PV guests, HVM guests can take advantage of hardware extensions that provide fast access to the underlying hardware on the host system. For more information on CPU virtualization extensions available in Amazon EC2, see Intel Virtualization Technology on the Intel website. HVM AMIs are required to take advantage of enhanced networking and GPU processing. In order to pass through instructions to specialized network and GPU devices, the OS needs to be able to have access to the native hardware platform; HVM virtualization provides this access. For more information, see Enhanced networking on Linux (p. 1124) and Linux accelerated computing instances (p. 345) .	No, they cannot take advantage of special hardware extensions such as enhanced networking or GPU processing.
Supported instance types	All current generation instance types support HVM AMIs.	The following previous generation instance types support PV AMIs: C1, C3, HS1, M1, M3, M2, and T1. Current generation instance types do not support PV AMIs.
Supported Regions	All Regions support HVM instances.	Asia Pacific (Tokyo), Asia Pacific (Singapore), Asia Pacific (Sydney), Europe (Frankfurt),

	HVM	PV
		Europe (Ireland), South America (São Paulo), US East (N. Virginia), US West (N. California), and US West (Oregon)
How to find	Verify that the virtualization type of the AMI is set to <code>hvm</code> , using the console or the describe-images command.	Verify that the virtualization type of the AMI is set to <code>paravirtual</code> , using the console or the describe-images command.

PV on HVM

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so operating systems that cannot be ported to run in a paravirtualized environment can still see performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same, or better, performance than paravirtual guests.

Boot modes

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

Default boot modes

In EC2, two variants of the boot mode software are supported: Legacy BIOS and Unified Extensible Firmware Interface (UEFI). By default, Intel and AMD instance types run on Legacy BIOS, and Graviton instance types run on UEFI.

Running Intel and AMD instances types on UEFI

[Most Intel and AMD instance types](#) can run on both UEFI and Legacy BIOS. To use UEFI, you must select an AMI with the boot mode parameter set to `uefi`, and the operating system contained in the AMI must be configured to support UEFI.

Purpose of the AMI boot mode parameter

The AMI boot mode parameter signals to EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to `uefi`, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch might be unsuccessful.

Warning

Setting the boot mode parameter does not automatically configure the operating system for the specified boot mode. The configuration is specific to the operating system. For the configuration instructions, see the manual for your operating system.

Possible boot mode parameter on an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: `uefi` or `legacy-bios`. Some AMIs do not have a boot mode parameter. For AMIs with no boot mode

parameter, the instances launched from these AMIs use the default value of the instance type—**uefi** on Graviton, and **legacy-bios** on all Intel and AMD instance types.

Considerations

- Default boot modes:
 - Intel and AMD instance types: Legacy BIOS
 - Graviton instance types: UEFI
- Intel and AMD instance types that support UEFI, in addition to Legacy BIOS:
 - Virtualized: C5, C5a, C5ad, C5d, C5n, D3, D3en, G4, I3en, M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6i, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, T3, T3a, and z1d
- UEFI Secure Boot is currently not supported.

Requirements for launching an instance with UEFI

To launch an instance in UEFI mode, you must select an instance type that supports UEFI, and configure the AMI and the OS for UEFI, as follows:

- **Instance type** – When launching an instance, you must select an instance type that supports UEFI. For more information, see [Determine the supported boot modes of an instance type \(p. 112\)](#).
- **AMI** – When launching an instance, you must select an AMI that is configured for UEFI. The AMI must be configured as follows:
 - **OS** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the instance launch will fail. For more information, see [Determine the boot mode of the OS \(p. 114\)](#).
 - **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to **uefi**. For more information, see [Determine the boot mode parameter of an AMI \(p. 111\)](#).

AWS does not provide AMIs that are already configured to support UEFI. You must [configure the AMI \(p. 115\)](#), import the AMI through [VM Import/Export](#), or import the AMI through [CloudEndure](#).

Determine the boot mode parameter of an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: **uefi** and **legacy-bios**.

Some AMIs do not have a boot mode parameter. When an AMI has no boot mode parameter, the instances launched from the AMI use the default value of the instance type, which is **uefi** on Graviton, and **legacy-bios** on Intel and AMD instance types.

To determine the boot mode parameter of an AMI (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select the AMI.
3. On the **Details** tab, inspect the **Boot mode** field.

To determine the boot mode parameter of an AMI when launching an instance (console)

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the **Boot mode** field. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 581\)](#).

To determine the boot mode parameter of an AMI (AWS CLI version 1.19.34 and later and version 2.1.32 and later)

Use the [describe-images](#) command to determine the boot mode of an AMI.

```
aws ec2 --region us-east-1 describe-images --image-id ami-0abcdef1234567890
```

Expected output

```
{
  "Images": [
    {
      ...
      ],
      "EnaSupport": true,
      "Hypervisor": "xen",
      "ImageOwnerAlias": "amazon",
      "Name": "UEFI_Boot_Mode_Enabled-Windows_Server-2016-English-Full-
Base-2020.09.30",
      "RootDeviceName": "/dev/sda1",
      "RootDeviceType": "ebs",
      "SriovNetSupport": "simple",
      "VirtualizationType": "hvm",
      "BootMode": "uefi"
    }
  ]
}
```

Determine the supported boot modes of an instance type

To determine the supported boot modes of an instance type (AWS CLI version 1.19.34 and later and version 2.1.32 and later)

Use the [describe-instance-types](#) command to determine the supported boot modes of an instance type. By including the `--query` parameter, you can filter the output. In this example, the output is filtered to return only the supported boot modes.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.

```
aws ec2 --region us-east-1 describe-instance-types --instance-types m5.2xlarge --query
"InstanceTypes[*].SupportedBootModes"
```

Expected output

```
[  
  [  
    "legacy-bios",  
    "uefi"  
  ]  
]
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```
aws ec2 --region us-east-1 describe-instance-types --instance-types t2.xlarge --query  
"InstanceTypes[*].SupportedBootModes"
```

Expected output

```
[  
  [  
    "legacy-bios"  
  ]  
]
```

Determine the boot mode of an instance

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:

- An AMI with a boot mode parameter of **uefi** creates an instance with a boot mode parameter of **uefi**.
- An AMI with a boot mode parameter of **legacy-bios** creates an instance with no boot mode parameter. An instance with no boot mode parameter uses its default value, which is **legacy-bios** in this case.
- An AMI with no boot mode parameter value creates an instance with no boot mode parameter value.

The value of the instance's boot mode parameter determines the mode in which it boots. If there is no value, the default boot mode is used, which is **uefi** on Graviton, and **legacy-bios** on Intel and AMD instance types.

To determine the boot mode of an instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, inspect the **Boot mode** field.

To determine the boot mode of an instance (AWS CLI version 1.19.34 and later and version 2.1.32 and later)

Use the [describe-instances](#) command to determine the boot mode of an instance.

```
aws ec2 --region us-east-1 describe-instances --instance-ids i-1234567890abcdef0
```

Expected output

```
{  
  "Reservations": [  
    {
```

```
{  
    "Groups": [],  
    "Instances": [  
        {  
            "AmiLaunchIndex": 0,  
            "ImageId": "ami-0e2063e7f6dc3bee8",  
            "InstanceId": "i-1234567890abcdef0",  
            "InstanceType": "m5.2xlarge",  
            "...  
        },  
        {"BootMode": "uefi"}  
    ],  
    "OwnerId": "1234567890",  
    "ReservationId": "r-1234567890abcdef0"  
}  
}]  
}
```

Determine the boot mode of the OS

The boot mode of the OS guides EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance via SSH.

To determine the boot mode of the instance's OS

1. [Connect to your Linux instance using SSH \(p. 614\)](#).
2. To view the boot mode of the OS, try one of the following:
 - Run the following command.

```
[ec2-user ~]$ sudo /usr/sbin/efibootmgr
```

Expected output from an instance booted in UEFI boot mode

```
BootCurrent: 0001  
Timeout: 0 seconds  
BootOrder: 0000,0001,0002  
Boot0000* UIApp  
Boot0001* UEFI Amazon Elastic Block Store vol-xyz  
Boot0002* EFI Internal Shell
```

- Run the following command to verify the existence of the `/sys/firmware/efi` directory. This directory exists only if the instance boots using UEFI. If this directory doesn't exist, the command returns `Legacy BIOS Boot Detected`.

```
[ec2-user ~]$ [ -d /sys/firmware/efi ] && echo "UEFI Boot Detected" || echo "Legacy BIOS Boot Detected"
```

Expected output from an instance booted in UEFI boot mode

```
UEFI Boot Detected
```

Expected output from an instance booted in Legacy BIOS boot mode

```
Legacy BIOS Boot Detected
```

- Run the following command to verify that EFI appears in the `dmesg` output.

```
[ec2-user ~]$ dmesg | grep -i "EFI"
```

Expected output from an instance booted in UEFI boot mode

```
[    0.000000] efi: Getting EFI parameters from FDT:  
[    0.000000] efi: EFI v2.70 by EDK II
```

Set the boot mode of an AMI

When you create an AMI using the [register-image](#) command, you can set the boot mode of the AMI to either `uefi` or `legacy-bios`.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you need to perform a number of steps: First, modify the instance's volume and OS to support the selected boot mode. Then, create a snapshot of the volume. Finally, use [register-image](#) to create the AMI using the snapshot.

You can't set the boot mode of an AMI using the [create-image](#) command. With [create-image](#), the AMI inherits the boot mode of the EC2 instance used for creating the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the AMI boot mode will be configured as `legacy-bios`.

Warning

Before proceeding with these steps, you must first make suitable modifications to the instance's volume and OS to support booting via the selected boot mode; otherwise, the resulting AMI will not be usable. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

To set the boot mode of an AMI (AWS CLI version 1.19.34 and later and version 2.1.32 and later)

- Make suitable modifications to the instance's volume and OS to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

Note

If you don't perform this step, the AMI will not be usable.

- To find the volume ID of the instance, use the [describe-instances](#) command. You'll create a snapshot of this volume in the next step.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

Expected output

```
...  
        "BlockDeviceMappings": [  
            {  
                "DeviceName": "/dev/sda1",  
                "Ebs": {  
                    "AttachTime": "",  
                    "DeleteOnTermination": true,  
                    "Status": "attached",  
                    "VolumeId": "vol-1234567890abcdef0"  
                }  
            }  
        ]
```

```
 }  
 ...
```

3. To create a snapshot of the volume, use the [create-snapshot](#) command. Use the volume ID from the previous step.

```
aws ec2 create-snapshot --region us-east-1 --volume-id vol-1234567890abcdef0  
--description "add text"
```

Expected output

```
{  
    "Description": "add text",  
    "Encrypted": false,  
    "OwnerId": "123",  
    "Progress": "",  
    "SnapshotId": "snap-01234567890abcdef",  
    "StartTime": "",  
    "State": "pending",  
    "VolumeId": "vol-1234567890abcdef0",  
    "VolumeSize": 30,  
    "Tags": []  
}
```

4. Note the snapshot ID in the output from the previous step.
5. Wait until the snapshot creation is completed before going to the next step. To query the state of the snapshot, use the [describe-snapshots](#) command.

```
aws ec2 describe-snapshots --region us-east-1 --snapshot-ids snap-01234567890abcdef
```

Example output

```
{  
    "Snapshots": [  
        {  
            "Description": "This is my snapshot",  
            "Encrypted": false,  
            "VolumeId": "vol-049df61146c4d7901",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2019-02-28T21:28:32.000Z",  
            "Progress": "100%",  
            "OwnerId": "012345678910",  
            "SnapshotId": "snap-01234567890abcdef",  
            ...  
        }  
    ]  
}
```

6. To create a new AMI, use the [register-image](#) command. Use the snapshot ID that you noted in the earlier step. To set the boot mode to UEFI, add the `--boot-mode uefi` parameter to the command.

```
aws ec2 register-image \  
    --region us-east-1 \  
    --description "add description" \  
    --name "add name" \  
    --block-device-mappings "DeviceName=/dev/  
    sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \  
    --architecture x86_64 \  
    --root-device-name /dev/sda1 \  
    --virtualization-type hvm \  
    --ena-support \  
    --
```

```
--boot-mode uefi
```

Expected output

```
{  
  "ImageId": "ami-new_ami_123"  
}
```

7. To verify that the newly-created AMI has the boot mode that you specified in the previous step, use the [describe-images](#) command.

```
aws ec2 describe-images --region us-east-1 --image-id ami-new_ami_123
```

Expected output

```
{  
  "Images": [  
    {  
      "Architecture": "x86_64",  
      "CreationDate": "2021-01-06T14:31:04.000Z",  
      "ImageId": "ami-new_ami_123",  
      "ImageLocation": "",  
      ...  
      "BootMode": "uefi"  
    }  
  ]  
}
```

8. Launch a new instance using the newly-created AMI. All new instances created from this AMI will inherit the same boot mode.
9. To verify that the new instance has the expected boot mode, use the [describe-instances](#) command.

UEFI variables

When you launch an instance where the boot mode is set to UEFI, a key-value store for variables is created. The store can be used by UEFI and the instance operating system for storing UEFI variables.

UEFI variables are used by the boot loader and the OS to configure early system startup. They allow the OS to manage certain settings of the boot process, like the boot order.

Warning

Operating systems often provide read access to local processes for any UEFI variable. You should never store sensitive data, such as passwords or personally identifiable information, in the UEFI variable store.

Find a Linux AMI

Before you can launch an instance, you must select an AMI to use. As you select an AMI, consider the following requirements you might have for the instances that you'll launch:

- The Region
- The operating system
- The architecture: 32-bit (`i386`), 64-bit (`x86_64`), or 64-bit ARM (`arm64`)
- The root device type: Amazon EBS or instance store

- The provider (for example, Amazon Web Services)
- Additional software (for example, SQL server)

If you need to find a Windows AMI, see [Find a Windows AMI](#) in the *Amazon EC2 User Guide for Windows Instances*.

If you need to find a Ubuntu AMI, see their [EC2 AMI Locator](#).

If you need to find a RedHat AMI, see the RHEL [knowledgebase article](#).

Find a Linux AMI using the Amazon EC2 console

You can find Linux AMIs using the Amazon EC2 console. You can select from the list of AMIs when you use the launch wizard to launch an instance, or you can search through all available AMIs using the [Images](#) page. AMI IDs are unique to each AWS Region.

To find a Linux AMI using the launch instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. On the **Quick Start** tab, select from one of the commonly used AMIs in the list. If you don't see the AMI that you need, choose the **My AMIs**, **AWS Marketplace**, or **Community AMIs** tab to find additional AMIs. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 581\)](#).

To find a Linux AMI using the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **AMIs**.
4. (Optional) Use the Filter and Search options to scope the list of displayed AMIs to see only the AMIs that interest you. For example, to list all Linux AMIs provided by AWS, choose **Public images**. Then use the Search options to further scope the list of displayed AMIs. Choose the Search bar and, from the menu, choose **Owner alias**, then the = operator, and then the value **amazon**. Choose the Search bar again to choose **Platform**, then the = operator, and then the operating system from the list provided.
5. (Optional) Choose the **Preferences** icon (new console) or **Show/Hide Columns** icon (old console) to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties on the **Details** tab.
6. Before you select an AMI, it's important that you check whether it's backed by instance store or by Amazon EBS and that you are aware of the effects of this difference. For more information, see [Storage for the root device \(p. 106\)](#).

7. To launch an instance from this AMI, select it and then choose **Launch instance from image** (new console) or **Launch** (old console). For more information about launching an instance using the console, see [Launching your instance from an AMI \(p. 582\)](#). If you're not ready to launch the instance now, make note of the AMI ID for later.

Find an AMI using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to list only the Linux AMIs that meet your needs. After locating an AMI that meets your needs, make note of its ID so that you can use it to launch instances. For more information, see [Launching an Instance Using the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The [describe-images](#) command supports filtering parameters. For example, use the `--owners` parameter to display public AMIs owned by Amazon.

```
aws ec2 describe-images --owners self amazon
```

You can add the following filter to the previous command to display only AMIs backed by Amazon EBS.

```
--filters "Name=root-device-type,Values=ebs"
```

Important

Omitting the `--owners` flag from the `describe-images` command will return all images for which you have launch permissions, regardless of ownership.

Find the latest Amazon Linux AMI using Systems Manager

Amazon EC2 provides AWS Systems Manager public parameters for AWS-maintained public AMIs that you can use when launching instances. For example, the EC2-provided parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions and always points to the latest version of the Amazon Linux 2 AMI in a given Region.

The Amazon EC2 AMI public parameters are available from the following path:

```
/aws/service/ami-amazon-linux-latest
```

You can view a list of all Linux AMIs in the current AWS Region by using the following command in the AWS CLI.

```
aws ssm get-parameters-by-path --path /aws/service/ami-amazon-linux-latest --query "Parameters[ ].Name"
```

To launch an instance using a public parameter

The following example uses the EC2-provided public parameter to launch an `m5.xlarge` instance using the latest Amazon Linux 2 AMI.

To specify the parameter in the command, use the following syntax: `resolve:ssm:public-parameter`, where `resolve:ssm` is the standard prefix and `public-parameter` is the path and name of the public parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances  
  --image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2  
  --instance-type m5.xlarge  
  --key-name MyKeyPair
```

For more information, see [Using public parameters in the AWS Systems Manager User Guide](#) and [Query for the latest Amazon Linux AMI IDs Using AWS Systems Manager Parameter Store](#).

Use a Systems Manager parameter to find an AMI

When you launch an instance using the EC2 launch wizard in the console, you can either select an AMI from the list, or you can select an AWS Systems Manager parameter that points to an AMI ID. If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your application configuration values. For more information, see [AWS Systems Manager Parameter Store](#) in the *AWS Systems Manager User Guide*.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as `aws:ec2:image`. This data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see [Native parameter support for Amazon Machine Image IDs](#) in the *AWS Systems Manager User Guide*.

- [Limitations \(p. 122\)](#)

Use cases

By using Systems Manager parameters to point to AMI IDs, you can make it easier for your users to select the correct AMI when launching instances, and you can simplify the maintenance of automation code.

Easier for users

If you require instances to be launched using a specific AMI, and if that AMI is updated regularly, we recommend that you require your users to select a Systems Manager parameter to find the AMI. By requiring your users to select a Systems Manager parameter, you can ensure that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, `golden-ami`) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't need to know about the periodic updates to the AMI, because they continue to select the same Systems Manager parameter every time. By having users select a Systems Manager parameter, you make it easier for them to select the correct AMI for an instance launch.

Simplify automation code maintenance

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you change the AMI ID value in the

parameter so that it points to the latest AMI. The automation code that references the parameter doesn't need to be modified every time a new version of the AMI is created. This greatly simplifies maintenance of automation and helps drive down deployment costs.

Note

Running instances are not affected when you change the AMI ID to which the Systems Manager parameter points.

Launch an instance using a Systems Manager parameter

You can launch an instance using the console or the AWS CLI. Instead of specifying an AMI ID, you can specify an AWS Systems Manager parameter that points to an AMI ID.

To find a Linux AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Choose **Search by Systems Manager parameter** (at top right).
5. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
6. Choose **Search**. The AMIs that match the AMI ID appear in the list.
7. Select the AMI from the list, and choose **Select**.

For more information about launching an instance from an AMI using the launch wizard, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 581\)](#).

To launch an instance using an AWS Systems Manager parameter instead of an AMI ID (AWS CLI)

The following example uses the Systems Manager parameter `golden-ami` to launch an `m5.xlarge` instance. The parameter points to an AMI ID.

To specify the parameter in the command, use the following syntax: `resolve:ssm:/parameter-name`, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter name. Note that the parameter name is case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, `/amis/production/golden-ami`. You can omit the backslash if the parameter is not part of a hierarchy.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami
  --instance-type m5.xlarge
  ...
```

To launch an instance using a specific version of an AWS Systems Manager parameter (AWS CLI)

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows `resolve:ssm:parameter-name:version`, where `version` is the unique version number. By default, the latest version of the parameter is used when no version is specified.

The following example uses version 2 of the parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami:2
  --instance-type m5.xlarge
  ...
```

To launch an instance using a public parameter provided by AWS

Amazon EC2 provides Systems Manager public parameters for public AMIs provided by AWS. For example, the public parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions and always points to the latest version of the Amazon Linux 2 AMI in the Region.

```
aws ec2 run-instances
  --image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2
  --instance-type m5.xlarge
  ...
```

Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your IAM policy. `ssm:DescribeParameters` grants your IAM users the permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your IAM users the permission to get the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see [Use the EC2 launch wizard \(p. 1289\)](#).

Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, `golden-ami`). In each Region, point the Systems Manager parameter to an AMI in that Region.

Shared AMIs

A *shared AMI* is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source.

Amazon's public images have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

For information about creating an AMI, see [Create an instance store-backed Linux AMI](#) or [Create an Amazon EBS-backed Linux AMI](#). For information about building, delivering, and maintaining your applications on the AWS Marketplace, see the [AWS Marketplace Documentation](#).

Find shared AMIs

You can use the Amazon EC2 console or the command line to find shared AMIs.

AMIs are a regional resource. Therefore, when searching for a shared AMI (public or private), you must search for it from within the Region from which it is being shared. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 180\)](#).

- [Find a shared AMI \(AWS CLI\) \(p. 123\)](#)
- [Use shared AMIs \(p. 124\)](#)

Find a shared AMI (console)

To find a shared private AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Private images**. All AMIs that have been shared with you are listed. To granulate your search, choose the Search bar and use the filter options provided in the menu.

To find a shared public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**. To granulate your search, choose the Search bar and use the filter options provided in the menu.
4. Use filters to list only the types of AMIs that interest you. For example, choose **Owner :** and then choose **Amazon images** to display only Amazon's public images.

Find a shared AMI (AWS CLI)

Use the [describe-images](#) command (AWS CLI) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

Example: List all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

Example: List AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

Example: List AMIs owned by Amazon

The following command lists the AMIs owned by Amazon. Amazon's public AMIs have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

```
aws ec2 describe-images --owners amazon
```

Example: List AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

Example: Scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

Use shared AMIs

Before you use a shared AMI, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates `authorized_keys` files:

```
[ec2-user ~]$ sudo find / -name "authorized_keys" -print -exec cat {} \;
```

2. Disable password-based authentication for the root user. Open the `sshd_config` file and edit the `PermitRootLogin` line as follows:

```
PermitRootLogin without-password
```

Alternatively, you can disable the ability to log into the instance as the root user:

```
PermitRootLogin No
```

Restart the `sshd` service.

3. Check whether there are any other user accounts that are able to log in to your instance. Accounts with superuser privileges are particularly dangerous. Remove or lock the password of any unknown accounts.
4. Check for open ports that you aren't using and running network services listening for incoming connections.

5. To prevent preconfigured remote logging, you should delete the existing configuration file and restart the rsyslog service. For example:

```
[ec2-user ~]$ sudo rm /etc/rsyslog.conf  
[ec2-user ~]$ sudo service rsyslog restart
```

6. Verify that all cron jobs are legitimate.

If you discover a public AMI that you feel presents a security risk, contact the AWS security team. For more information, see the [AWS Security Center](#).

Make an AMI public

You can share your AMIs with other AWS accounts. To allow all AWS accounts to use an AMI to launch instances, make the AMI public. To allow only specific accounts to use the AMI to launch instances, see [Share an AMI with specific AWS accounts \(p. 133\)](#).

Topics

- [Considerations \(p. 125\)](#)
- [Share an AMI with all AWS accounts \(console\) \(p. 125\)](#)
- [Share an AMI with all AWS accounts \(AWS CLI\) \(p. 126\)](#)

Considerations

- AMIs with encrypted volumes cannot be made public.
- To avoid exposing sensitive data when you share an AMI, read the security considerations in [Guidelines for shared Linux AMIs \(p. 136\)](#) and follow the recommended actions.
- If an AMI has a product code, or contains a snapshot of an encrypted volume, you can't make it public; you can share the AMI only with specific AWS accounts.
- AMIs are a regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 180\)](#).
- You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.
- When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.

Share an AMI with all AWS accounts (console)

After you make an AMI public, it is available in **Community AMIs** when you launch an instance in the same Region using the console. Note that it can take a short while for an AMI to appear in **Community AMIs** after you make it public. It can also take a short while for an AMI to be removed from **Community AMIs** after you make it private again.

New console

To share a public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Edit AMI permissions**.

4. Choose **Public**, and then choose **Save changes**.

Old console

To share a public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Modify Image Permissions**.
4. Choose **Public**, and then choose **Save**.

Share an AMI with all AWS accounts (AWS CLI)

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts) or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the [modify-image-attribute](#) command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Add=[{Group=all}]"
```

2. To verify the launch permissions of the AMI, use the [describe-image-attribute](#) command.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Remove=[{Group=all}]"
```

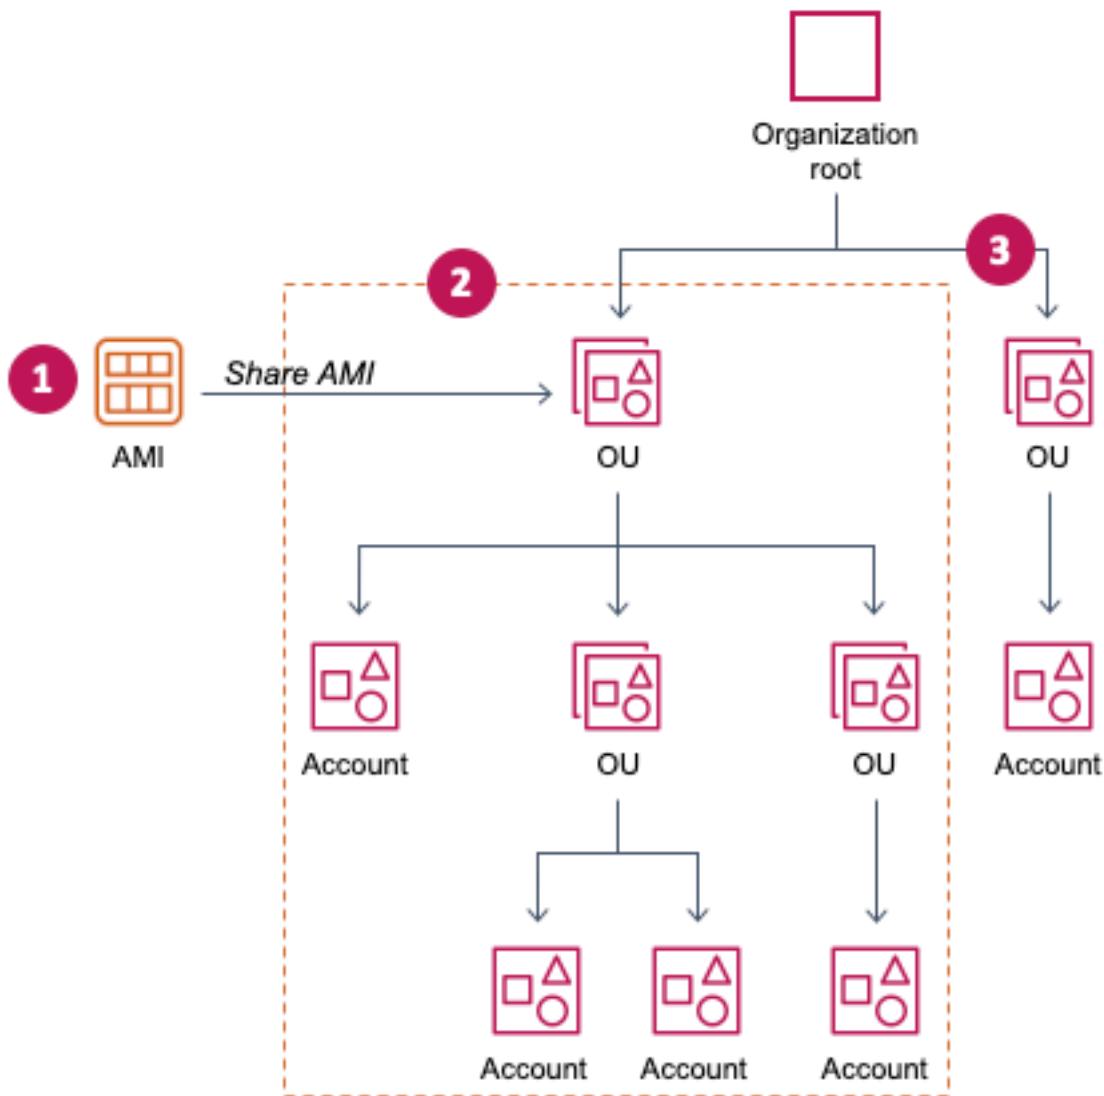

Share an AMI with specific organizations or organizational units

You can share an AMI with an organization or an organizational unit (OU), in addition to [sharing it with specific accounts \(p. 133\)](#).

An organization is an entity that you create to consolidate and centrally manage your AWS accounts. You can organize the accounts in a hierarchical, tree-like structure with a [root](#) at the top and [organizational units](#) nested under the root. Each account can be directly in the root, or placed in one of the OUs in

the hierarchy. For more information, see [AWS Organizations terminology and concepts](#) in the *AWS Organizations User Guide*.

When you share an AMI with an organization or an OU, all of the children accounts gain access to the AMI. For example, in the following diagram, the AMI is shared with a top-level OU (indicated by the arrow at the number 1). All of the OUs and accounts that are nested underneath that top-level OU (indicated by the dotted line at number 2) also have access to the AMI. The accounts in the organization and OU outside the dotted line (indicated by the number 3) do not have access to the AMI because they are not children of the OU that the AMI is shared with.

Considerations

- **No sharing limits** – The AMI owner can share an AMI with any organization or OU, including organizations and OUs that they're not a member of.

There is no limit to the number of organizations or OUs with which an AMI can be shared.

- **Tags** – User-defined tags that you attach to a shared AMI are available only to your AWS account and not to the AWS accounts in the other organizations and OUs that the AMI is shared with.

- **ARN format** – When specifying an organization or OU in a command, make sure to use the correct ARN format. You'll get an error if you specify only the ID, for example, if you specify only o-123example or ou-1234-5example.

Correct ARN formats:

- Organization ARN: arn:aws:organizations::*account-id*:organization/*organization-id*
- OU ARN: arn:aws:organizations::*account-id*:ou/*organization-id*/*ou-id*

Where:

- *account-id* is the 12-digit management account number, for example, 123456789012. If you don't know the management account number, you can describe the organization or the organizational unit to get the ARN, which includes the management account number. For more information, see [Get the ARN \(p. 132\)](#).
- *organization-id* is the organization ID, for example, o-123example.
- *ou-id* is the organizational unit ID, for example, ou-1234-5example.

For more information about the ARN format, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
 - The encrypted snapshots must be encrypted with a customer managed key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key. For more information, see [Share an Amazon EBS snapshot \(p. 1441\)](#).
 - If you share an AMI that is backed by encrypted snapshots, you must allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key \(p. 128\)](#).
- **Regional resource** – AMIs are a regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 180\)](#).
- **AMI use** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Allow organizations and OUs to use a KMS key

If you share an AMI that is backed by encrypted snapshots, you must also allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots.

Use the `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` keys to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be an IAM user, IAM role, federated user, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or OUs in AWS Organizations. For more example condition statements, see `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` in the *IAM User Guide*.

For information about editing a key policy, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide* and [Share a KMS key \(p. 1443\)](#).

To give an organization or OU permission to use a KMS key, add the following statement to the key policy.

```
{
```

```
"Sid": "Allow access for Org Admin",
"Effect": "Allow",
"Principal": "*",
>Action": [
    "kms:Describe*",
    "kms>List*",
    "kms:Get*",
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:PrincipalOrgID": "o-123example"
    }
}
}
```

To share a KMS key with multiple OUs, you can use a policy similar to the following example.

```
{
    "Sid": "Allow access for specific OUs and their descendants",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "kms:Describe*",
        "kms>List*",
        "kms:Get*",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:PrincipalOrgID": "o-123example"
        },
        "ForAnyValue:StringLike": {
            "aws:PrincipalOrgPaths": [
                "o-123example/r-ab12/ou-ab12-33333333/*",
                "o-123example/r-ab12/ou-ab12-22222222/*"
            ]
        }
    }
}
```

Share an AMI

You can use the Amazon EC2 console or the AWS CLI to share an AMI with an organization or OU.

Share an AMI (console)

To share an AMI with an organization or an OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.

4. Under **AMI availability**, choose **Private**.
5. Next to **Shared organizations/OUs**, choose **Add organization/OU ARN**.
6. For **Organization/OU ARN**, enter the organization ARN or OU ARN with which you want to share the AMI, and then choose **Share AMI**. Note that you must specify the full ARN, not just the ID.

To share this AMI with multiple organizations or OUs, repeat this step until you have added all of the required organizations or OUs.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key \(p. 128\)](#).

7. Choose **Save changes** when you're done.
8. (Optional) To view the organizations or OUs with which you have shared the AMI, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**. To find AMIs that are shared with you, see [Find shared AMIs \(p. 123\)](#).

Share an AMI (AWS CLI)

Use the [modify-image-attribute](#) command (AWS CLI) to share an AMI.

To share an AMI with an organization using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified organization. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example}]"
```

To share an AMI with an OU using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified OU. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationalUnitArn=arn:aws:organizations::123456789012:ou/o-123example/
ou-1234-5example}]"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key \(p. 128\)](#).

Stop sharing an AMI

You can use the Amazon EC2 console or the AWS CLI to stop sharing an AMI with an organization or OU.

Stop sharing an AMI (console)

To stop sharing an AMI with an organization or OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Under **Shared organizations/OUs**, select the organizations or OUs with which you want to stop sharing the AMI, and then choose **Remove selected**.
5. Choose **Save changes** when you're done.
6. (Optional) To confirm that you have stopped sharing the AMI with the organizations or OUs, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

Stop sharing an AMI (AWS CLI)

Use the [modify-image-attribute](#) or [reset-image-attribute](#) commands (AWS CLI) to stop sharing an AMI.

To stop sharing an AMI with an organization or OU using the AWS CLI

The [modify-image-attribute](#) command removes launch permissions for the specified AMI from the specified organization. Note that you must specify the ARN.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Remove=[{OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example}]"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts using the AWS CLI

The [reset-image-attribute](#) command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

Note

You can't stop sharing an AMI with a specific account if it's in an organization or OU with which an AMI is shared. If you try to stop sharing the AMI by removing launch permissions for the account, Amazon EC2 returns a success message. However, the AMI continues to be shared with the account.

View the organizations and OUs with which an AMI is shared

You can use the Amazon EC2 console or the AWS CLI to check with which organizations and OUs you've shared your AMI.

View the organizations and OUs with which an AMI is shared (console)

To check with which organizations and OUs you've shared your AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

To find AMIs that are shared with you, see [Find shared AMIs \(p. 123\)](#).

View the organizations and OUs with which an AMI is shared (AWS CLI)

You can check with which organizations and OUs you've shared your AMI by using the [describe-image-attribute](#) command (AWS CLI) and the `launchPermission` attribute.

To check with which organizations and OUs you've shared your AMI using the AWS CLI

The [describe-image-attribute](#) command describes the `launchPermission` attribute for the specified AMI, and returns the organizations and OUs with which you've shared the AMI.

```
aws ec2 describe-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

Example response

```
{
    "ImageId": "ami-0abcdef1234567890",
    "LaunchPermissions": [
        {
            "OrganizationalUnitArn": "arn:aws:organizations::111122223333:ou/o-123example/ou-1234-5example"
        }
    ]
}
```

Get the ARN

The organization and the organizational unit ARNs contain the 12-digit management account number. If you don't know the management account number, you can describe the organization and the organizational unit to get the ARN for each. In the following examples, 123456789012 is the management account number.

Before you can get the ARNs, you must have the permission to describe organizations and organizational units. The following policy provides the necessary permission.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "organizations:Describe*"
            ],
            "Resource": "*"
        }
    ]
}
```

To get the ARN of an organization

Use the [describe-organization](#) command and the `--query` parameter set to '`Organization.Arn`' to return only the organization ARN.

```
aws organizations describe-organization --query 'Organization.Arn'
```

Example response

```
"arn:aws:organizations::123456789012:organization/o-123example"
```

To get the ARN of an organizational unit

Use the [describe-organizational-unit](#) command, specify the OU ID, and set the --query parameter to 'OrganizationalUnit.Arn' to return only the organizational unit ARN.

```
aws organizations describe-organizational-unit --organizational-unit-id ou-1234-5example --query 'OrganizationalUnit.Arn'
```

Example response

```
"arn:aws:organizations::123456789012:ou/o-123example/ou-1234-5example"
```

Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need is the AWS account IDs.

Considerations

- **No sharing limits** – There is no limit to the number of AWS accounts with which an AMI can be shared.
- **Tags** – User-defined tags that you attach to a shared AMI are available only to your AWS account and not to the other accounts that the AMI is shared with.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
 - The encrypted snapshots must be encrypted with a customer managed key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key. For more information, see [Share an Amazon EBS snapshot \(p. 1441\)](#).
 - If you share an AMI that is backed by encrypted snapshots, you must allow the AWS accounts to use the customer managed keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key \(p. 128\)](#).
- **Regional resource** – AMIs are a regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 180\)](#).
- **AMI use** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Copying shared AMIs** – If users in another account want to copy a shared AMI, you must grant them read permissions for the storage that backs the AMI. For more information, see [Cross-account copying \(p. 185\)](#).
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Share an AMI (console)

New console

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Choose **Private**.
5. Under **Shared accounts**, choose **Add account ID**.
6. For **AWS account ID**, enter the AWS account ID with which you want to share the AMI, and then choose **Share AMI**.

To share this AMI with multiple accounts, repeat Steps 5 and 6 until you have added all the required account IDs.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1441\)](#).

7. Choose **Save changes** when you are done.
8. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs \(p. 123\)](#).

Old console

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Modify Image Permissions**.
4. Specify the AWS account number of the user with whom you want to share the AMI in the **AWS Account Number** field, then choose **Add Permission**.

To share this AMI with multiple users, repeat this step until you have added all the required users.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1441\)](#).

5. Choose **Save** when you are done.
6. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs \(p. 123\)](#).

Share an AMI (AWS CLI)

Use the [modify-image-attribute command \(AWS CLI\)](#) to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission "Add=[{UserId=123456789012}]"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1441\)](#).

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account:

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission "Remove=[{UserId=123456789012}]"
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

Use bookmarks

If you have created a public AMI, or shared an AMI with another AWS user, you can create a *bookmark* that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don't have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

To create a bookmark for your AMI

1. Type a URL with the following information, where *region* is the Region in which your AMI resides:

```
https://console.aws.amazon.com/ec2/v2/home?
region=region#LaunchInstanceWizard:ami=ami_id
```

For example, this URL launches an instance from the ami-0abcdef1234567890 AMI in the us-east-1 Region:

```
https://console.aws.amazon.com/ec2/v2/home?region=us-
east-1#LaunchInstanceWizard:ami=ami-0abcdef1234567890
```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, choose the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.

Guidelines for shared Linux AMIs

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.

Important

No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

Contents

- [Update the AMI tools before using them \(p. 136\)](#)
- [Disable password-based remote logins for root \(p. 136\)](#)
- [Disable local root access \(p. 137\)](#)
- [Remove SSH host key pairs \(p. 137\)](#)
- [Install public key credentials \(p. 138\)](#)
- [Disabling sshd DNS checks \(optional\) \(p. 139\)](#)
- [Identify yourself \(p. 139\)](#)
- [Protect yourself \(p. 139\)](#)

If you are building AMIs for AWS Marketplace, see [Best practices for building AMIs in the AWS Marketplace Seller Guide](#) for guidelines, policies, and best practices.

For additional information about sharing AMIs safely, see the following articles:

- [How To Share and Use Public AMIs in A Secure Manner](#)
- [Public AMI Publishing: Hardening and Clean-up Requirements](#)

Update the AMI tools before using them

For AMIs backed by instance store, we recommend that your AMIs download and upgrade the Amazon EC2 AMI creation tools before you use them. This ensures that new AMIs based on your shared AMIs have the latest AMI tools.

For [Amazon Linux 2](#), install the `aws-amitools-ec2` package and add the AMI tools to your PATH with the following command. For the [Amazon Linux AMI](#), `aws-amitools-ec2` package is already installed by default.

```
[ec2-user ~]$ sudo yum install -y aws-amitools-ec2 && export PATH=$PATH:/opt/aws/bin > /etc/profile.d/aws-amitools-ec2.sh && . /etc/profile.d/aws-amitools-ec2.sh
```

Upgrade the AMI tools with the following command:

```
[ec2-user ~]$ sudo yum upgrade -y aws-amitools-ec2
```

For other distributions, make sure you have the latest AMI tools.

Disable password-based remote logins for root

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.

To solve this problem, disable password-based remote logins for the root user.

To disable password-based remote logins for root

1. Open the /etc/ssh/sshd_config file with a text editor and locate the following line:

```
#PermitRootLogin yes
```

2. Change the line to:

```
PermitRootLogin without-password
```

The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

Disable local root access

When you work with shared AMIs, a best practice is to disable direct root logins. To do this, log into your running instance and issue the following command:

```
[ec2-user ~]$ sudo passwd -l root
```

Note

This command does not impact the use of sudo.

Remove SSH host key pairs

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in /etc/ssh. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

Remove all of the following key files that are present on your system.

- ssh_host_dsa_key
- ssh_host_dsa_key.pub
- ssh_host_key
- ssh_host_key.pub
- ssh_host_rsa_key
- ssh_host_rsa_key.pub
- ssh_host_ecdsa_key
- ssh_host_ecdsa_key.pub
- ssh_host_ed25519_key
- ssh_host_ed25519_key.pub

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

Warning

Secure deletion utilities such as **shred** may not remove all copies of a file from your storage media. Hidden copies of files may be created by journalling file systems (including Amazon Linux default ext4), snapshots, backups, RAID, and temporary caching. For more information see the [shred documentation](#).

Important

If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.

Install public key credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the `RunInstances` API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to `CreateKeyPair` or `ImportKeyPair`) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to `/root/.ssh/authorized_keys` (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the `cloud-init` package to inject public key credentials for a configured user. If your distribution does not support `cloud-init`, you can add the following code to a system start-up script (such as `/etc/rc.local`) to pull in the public key you specified at launch for the root user.

Note

In the following example, the IP address `http://169.254.169.254/` is a link-local address and is valid only from the instance.

IMDSv2

```
if [ ! -d /root/.ssh ] ; then
    mkdir -p /root/.ssh
    chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" ` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key > /tmp/my-key
if [ $? -eq 0 ] ; then
    cat /tmp/my-key >> /root/.ssh/authorized_keys
    chmod 700 /root/.ssh/authorized_keys
    rm /tmp/my-key
fi
```

IMDSv1

```
if [ ! -d /root/.ssh ] ; then
    mkdir -p /root/.ssh
    chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key > /tmp/my-key
if [ $? -eq 0 ] ; then
    cat /tmp/my-key >> /root/.ssh/authorized_keys
    chmod 700 /root/.ssh/authorized_keys
    rm /tmp/my-key
fi
```

This can be applied to any user account; you do not need to restrict it to `root`.

Note

Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key's inclusion, you must clear out (or delete) the `authorized_keys` file or exclude this file from rebundling.

Disabling sshd DNS checks (optional)

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

To disable sshd DNS checks

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

```
#UseDNS yes
```

2. Change the line to:

```
UseDNS no
```

Note

The location of this configuration file can differ for your distribution or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

Identify yourself

Currently, there is no easy way to know who provided a shared AMI, because each AMI is represented by an account ID.

We recommend that you post a description of your AMI, and the AMI ID, in the [Amazon EC2 forum](#). This provides a convenient central location for users who are interested in trying new shared AMIs.

Protect yourself

We recommend against storing sensitive data or software on any AMI that you share. Users who launch a shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you to avoid some easily overlooked security risks:

- We recommend using the `--exclude directory` option on `ec2-bundle-vol` to skip any directories and subdirectories that contain secret information that you would not like to include in your bundle. In particular, exclude all user-owned SSH public/private key pairs and SSH `authorized_keys` files when bundling the image. The Amazon public AMIs store these in `/root/.ssh` for the root account, and `/home/user_name/.ssh/` for regular user accounts. For more information, see [ec2-bundle-vol \(p. 166\)](#).
- Always delete the shell history before bundling. If you attempt more than one bundle upload in the same AMI, the shell history contains your secret access key. The following example should be the last command you run before bundling from within the instance.

```
[ec2-user ~]$ shred -u ~/.history
```

Warning

The limitations of `shred` described in the warning above apply here as well.

Be aware that bash writes the history of the current session to the disk on exit. If you log out of your instance after deleting `~/.bash_history`, and then log back in, you will find that

`~/.bash_history` has been re-created and contains all of the commands you ran during your previous session.

Other programs besides bash also write histories to disk. Use caution and remove or exclude unnecessary dot-files and dot-directories.

- Bundling a running instance requires your private key and X.509 certificate. Put these and other credentials in a location that is not bundled (such as the instance store).

Paid AMIs

A *paid AMI* is an AMI that you can purchase from a developer.

Amazon EC2 integrates with AWS Marketplace, enabling developers to charge other Amazon EC2 users for the use of their AMIs or to provide support for instances.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories, such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the [AWS Marketplace](#) site.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m1.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

Important

Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see [Selling in AWS Marketplace](#). AWS Marketplace supports AMIs backed by Amazon EBS.

- [Bills for paid and supported AMIs \(p. 143\)](#)
- [Manage your AWS Marketplace subscriptions \(p. 143\)](#)

Sell your AMI

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see [Selling in AWS Marketplace](#).

Find a paid AMI

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use [AWS Marketplace](#), the Amazon EC2 console, or the command line. Alternatively, a developer might let you know about a paid AMI themselves.

Find a paid AMI using the console

To find a paid AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Choose **Public images** for the first filter.
4. In the Search bar, choose **Owner**, then **AWS Marketplace**.
5. If you know the product code, choose **Product Code**, then type the product code.

Find a paid AMI using AWS Marketplace

To find a paid AMI using AWS Marketplace

1. Open [AWS Marketplace](#).
2. Enter the name of the operating system in the search box, and click **Go**.
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either **AMI** or **Software as a Service**.

Find a paid AMI using the AWS CLI

You can find a paid AMI using the following [describe-images](#) command (AWS CLI).

```
aws ec2 describe-images
  --owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from `describe-images` includes an entry for the product code like the following:

```
"ProductCodes": [
  {
    "ProductCodeId": "product_code",
    "ProductCodeType": "marketplace"
  }
],
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
aws ec2 describe-images
  --owners aws-marketplace \
  --filters "Name=product-code,Values=product_code" \
  --query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

Purchase a paid AMI

You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you're first asked to log into AWS, and then you can purchase the AMI.

Purchase a paid AMI using the console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see [Launch an AWS Marketplace instance \(p. 610\)](#).

Subscribe to a product using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. There are two ways to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website:** You can launch preconfigured software quickly with the 1-Click deployment feature.
- **Amazon EC2 launch wizard:** You can search for an AMI and launch an instance directly from the wizard. For more information, see [Launch an AWS Marketplace instance \(p. 610\)](#).

Get the product code for your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. For more information about retrieving metadata, see [Instance metadata and user data \(p. 726\)](#).

To retrieve a product code, use the following command:

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/product-codes
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/product-codes
```

If the instance has a product code, Amazon EC2 returns it.

Use paid support

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

Important

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.

To associate a product code with your AMI, use one of the following commands, where *ami_id* is the ID of the AMI and *product_code* is the product code:

- [modify-image-attribute \(AWS CLI\)](#)

```
aws ec2 modify-image-attribute --image-id ami_id --product-codes "product_code"
```

- [Edit-EC2ImageAttribute](#) (AWS Tools for Windows PowerShell)

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami_id -ProductCode product_code
```

After you set the product code attribute, it cannot be changed or removed.

Bills for paid and supported AMIs

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see [Paying for products](#) in the *AWS Marketplace Buyer Guide*.

Manage your AWS Marketplace subscriptions

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

To check your subscription details

1. Log in to the [AWS Marketplace](#).
2. Choose **Your Marketplace Account**.
3. Choose **Manage your software subscriptions**.
4. All your current subscriptions are listed. Choose **Usage Instructions** to view specific instructions for using the product, for example, a user name for connecting to your running instance.

To cancel an AWS Marketplace subscription

1. Ensure that you have terminated any instances running from the subscription.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. In the navigation pane, choose **Instances**.
 - c. Select the instance, and choose **Actions, Instance State, Terminate**.
 - d. Choose **Yes, Terminate** when prompted for confirmation.
2. Log in to the [AWS Marketplace](#), and choose **Your Marketplace Account**, then **Manage your software subscriptions**.
3. Choose **Cancel subscription**. You are prompted to confirm your cancellation.

Note

After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

Create an AMI

You can create Amazon EBS-back Linux AMIs and instance store-backed AMIs.

Topics

- [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#)
- [Create an instance store-backed Linux AMI \(p. 149\)](#)

For information about how to create a Windows AMI, see [Create a custom Windows AMI](#).

Create an Amazon EBS-backed Linux AMI

To create an Amazon EBS-backed Linux AMI, start from an instance that you've launched from an existing Amazon EBS-backed Linux AMI. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the [AWS Server Migration Service](#) or [VM Import/Export](#), or any other AMI you can access. After you customize the instance to suit your needs, create and register a new AMI, which you can use to launch new instances with these customizations.

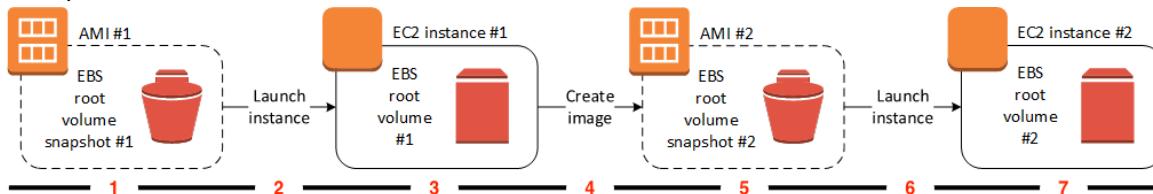

The procedures described below work for Amazon EC2 instances backed by encrypted Amazon Elastic Block Store (Amazon EBS) volumes (including the root volume) as well as for unencrypted volumes.

The AMI creation process is different for instance store-backed AMIs. For information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see [Storage for the root device \(p. 106\)](#). For information about creating an instance store-backed Linux AMI, see [Create an instance store-backed Linux AMI \(p. 149\)](#).

For information about creating an Amazon EBS-backed Windows AMI, see [Create an Amazon EBS-backed Windows AMI](#) in the [Amazon EC2 User Guide for Windows Instances](#).

Overview of creating Amazon EBS-backed AMIs

The following diagram summarizes the process for creating an Amazon EBS-backed AMI from a running EC2 instance: Start with an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The numbers in the diagram match the numbers in the description that follows.

Find an existing AMI that is similar to the AMI that you'd like to create. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the [AWS Server Migration](#)

[Service or VM Import/Export](#), or any other AMI you can access. You'll customize this AMI for your needs.

In the diagram, **EBS root volume snapshot #1** indicates that the AMI is an Amazon EBS-backed AMI and that information about the root volume is stored in this snapshot.

2 – Launch instance from existing AMI

The way to configure an AMI is to launch an instance from the AMI on which you'd like to base your new AMI, and then customize the instance (indicated at **3** in the diagram). Then, you'll create a new AMI that includes the customizations (indicated at **4** in the diagram).

3 – EC2 instance #1: Customize the instance

Connect to your instance and customize it for your needs. Your new AMI will include these customizations.

You can perform any of the following actions on your instance to customize it:

- Install software and applications
- Copy data
- Reduce start time by deleting temporary files, defragmenting your hard drive, and zeroing out free space
- Attach additional EBS volumes

4 – Create image

When you create an AMI from an instance, Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you're confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as XFS, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.

During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You're charged for the snapshots until you [deregister the AMI \(p. 196\)](#) and delete the snapshots. If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instances that support [Amazon EBS encryption \(p. 1542\)](#).

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You might find it more efficient to create snapshots of your volumes before creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same). For more information, see [Create Amazon EBS snapshots \(p. 1407\)](#).

5 – AMI #2: New AMI

After the process completes, you have a new AMI and snapshot (**snapshot #2**) created from the root volume of the instance. If you added instance-store volumes or EBS volumes to the instance, in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes.

Amazon EC2 automatically registers the AMI for you.

6 – Launch instance from new AMI

You can use the new AMI to launch an instance.

7 – EC2 instance #2: New instance

When you launch an instance using the new AMI, Amazon EC2 creates a new EBS volume for the instance's root volume using the snapshot. If you added instance-store volumes or EBS volumes when you customized the instance, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI

automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see [Block device mappings \(p. 1654\)](#).

When you create a new instance from an EBS-backed AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see [Initialize Amazon EBS volumes \(p. 1593\)](#).

Create a Linux AMI from an instance

You can create an AMI using the AWS Management Console or the command line.

Console

To create an AMI from an instance using the console

1. Start with an existing AMI.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. In the navigation pane, under **Images**, choose **AMIs**.
 - c. Select an appropriate EBS-backed AMI to serve as a starting point for your new AMI.
2. Launch an instance from the AMI.

Choose **Launch instance from image** (new console) or **Launch** (old console) to launch an instance of the EBS-backed AMI that you've selected. Accept the default values as you step through the wizard. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

3. Customize the instance.

While the instance is running, connect to it. You can perform any of the following actions on your instance to customize it for your needs:

- Install software and applications
- Copy data
- Reduce start time by deleting temporary files, defragmenting your hard drive, and zeroing out free space
- Attach additional EBS volumes

(Optional) Create snapshots of all the volumes attached to your instance. For more information about creating snapshots, see [Create Amazon EBS snapshots \(p. 1407\)](#).

4. Create an AMI from the instance.

- a. In the navigation pane, choose **Instances**, select your instance, and then choose **Actions**, **Image and templates**, **Create image**.

Tip

If this option is disabled, your instance isn't an Amazon EBS-backed instance.

- b. On the **Create image** page, specify the following information, and then choose **Create image**.

- **Image name** – A unique name for the image.
- **Image description** – An optional description of the image, up to 255 characters.
- **No reboot** – This option is not selected by default, so that when you choose **Create image**, Amazon EC2 shuts down the instance, takes snapshots of any attached volumes,

creates and registers the AMI, and then reboots the instance. If you're confident that your instance is in a consistent state appropriate for image creation, select **Enable** to avoid having your instance shut down.

Warning

If you select **Enable**, the AMI will be crash consistent (all the volumes are snapshotted at the same time), but *not* application consistent (all the operating system buffers are not flushed to disk before the snapshots are created).

- **Instance volumes** – The fields in this section enable you to modify the root volume, and add additional Amazon EBS and instance store volumes.
 - The root volume is defined in the first row. To change the size of the root volume, for **Size**, enter the required value.
 - If you select **Delete on termination**, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear **Delete on termination**, when you terminate the instance, the EBS volume is not deleted. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).
 - To add an EBS volume, choose **Add volume** (which adds a new row). For **Volume type**, choose **EBS**, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
 - To add an instance store volume, see [Add instance store volumes to an AMI \(p. 1631\)](#). When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.
- **Tags** – You can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.
 - To tag the AMI and the snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the AMI and every snapshot that is created.
 - To tag the AMI and the snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the AMI and the snapshots that are created. However, all the snapshots get the same tags; you can't tag each snapshot with a different tag.

To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

- c. To view the status of your AMI while it is being created, in the navigation pane, choose **AMIs**. Initially, the status is **Pending** but should change to **Available** after a few minutes.
5. (Optional) To view the snapshot that was created for the new AMI, choose **Snapshots**. When you launch an instance from this AMI, we use this snapshot to create its root device volume.
6. Launch an instance from your new AMI.

For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

The new running instance contains all of the customizations that you applied in the previous steps.

AWS CLI

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [create-image \(AWS CLI\)](#)
- [New-EC2Image \(AWS Tools for Windows PowerShell\)](#)

Create a Linux AMI from a snapshot

If you have a snapshot of the root device volume of an instance, you can create an AMI from this snapshot using the AWS Management Console or the command line.

New console

To create an AMI from a snapshot using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot from which to create the AMI and choose **Actions, Create image from snapshot**.
4. For **Image name**, enter a descriptive name for the image.
5. For **Description**, enter a brief description for the image.
6. For **Architecture**, choose the image architecture. Choose **i386** for 32-bit, **x86_64** for 64-bit, **ARM64** for 64-bit ARM, or **x86_64** for 64-bit macOS.
7. For **Root device name**, enter the device name to use for the root device volume. For more information, see [Device names on Linux instances \(p. 1652\)](#).
8. For **Virtualization type**, choose the virtualization type to be used by instances launched from this AMI. For more information, see [Linux AMI virtualization types \(p. 108\)](#).
9. (For paravirtual virtualization only) For **Kernel ID**, select the operating system kernel for the image. If you're using a snapshot of the root device volume of an instance, select the same kernel ID as the original instance. If you're unsure, use the default kernel.
10. (For paravirtual virtualization only) For **RAM disk ID**, select the RAM disk for the image. If you select a specific kernel, you may need to select a specific RAM disk with the drivers to support it.
11. (Optional) In the **Block device mappings** section, customize the root volume and add additional data volumes.

For each volume, you can specify the size, type, performance characteristics, the behavior of delete on termination, and encryption status. For the root volume, the size cannot be smaller than the size of the snapshot.

12. Choose **Create image**.

Old console

To create an AMI from a snapshot using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Elastic Block Store**, choose **Snapshots**.
3. Choose the snapshot and choose **Actions, Create Image**.
4. In the **Create Image from EBS Snapshot** dialog box, complete the fields to create your AMI, then choose **Create**. If you're re-creating a parent instance, then choose the same options as the parent instance.
 - **Architecture:** Choose **i386** for 32-bit or **x86_64** for 64-bit.
 - **Root device name:** Enter the appropriate name for the root volume. For more information, see [Device names on Linux instances \(p. 1652\)](#).
 - **Virtualization type:** Choose whether instances launched from this AMI use paravirtual (PV) or hardware virtual machine (HVM) virtualization. For more information, see [Linux AMI virtualization types \(p. 108\)](#).

- (PV virtualization type only) **Kernel ID** and **RAM disk ID**: Choose the AKI and ARI from the lists. If you choose the default AKI or don't choose an AKI, you must specify an AKI every time you launch an instance using this AMI. In addition, your instance may fail the health checks if the default AKI is incompatible with the instance.
- (Optional) **Block Device Mappings**: Add volumes or expand the default size of the root volume for the AMI. For more information about resizing the file system on your instance for a larger volume, see [Extend a Linux file system after resizing a volume \(p. 1538\)](#).

AWS CLI

To create an AMI from a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [register-image \(AWS CLI\)](#)
- [Register-EC2Image \(AWS Tools for Windows PowerShell\)](#)

Launch an instance from an AMI you created

You can launch an instance from an AMI that you created from an instance or snapshot.

To launch an instance from your AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Set the filter to **Owned by me** and select your AMI.
4. Choose **Actions, Launch**.
5. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

Create an instance store-backed Linux AMI

The AMI that you specify when you launch your instance determines the type of root device volume.

To create an instance store-backed Linux AMI, start from an instance that you've launched from an existing instance store-backed Linux AMI. After you've customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.

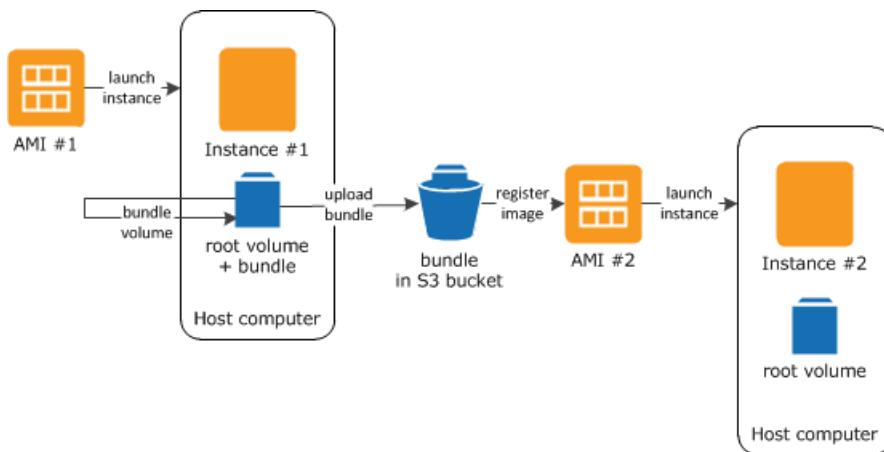

Important

Only the following instance types support an instance store volume as the root device: C3, D2, G2, I2, M3, and R3.

The AMI creation process is different for Amazon EBS-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see [Storage for the root device \(p. 106\)](#). If you need to create an Amazon EBS-backed Linux AMI, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#).

Overview of the creation process for instance store-backed AMIs

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (`image.manifest.xml`) and files (`image.part.xx`) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

Note

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see [Controlling ownership of uploaded objects using S3 Object Ownership](#).

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see [Deregister your Linux AMI \(p. 196\)](#).

If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see [Block device mappings \(p. 1654\)](#).

Prerequisites

Before you can create an AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see [Set up the AMI tools \(p. 151\)](#).
- Install the AWS CLI. For more information, see [Getting Set Up with the AWS Command Line Interface](#).
- Ensure that you have an S3 bucket for the bundle, and that your bucket has ACLs enabled.

To create an S3 bucket, open the Amazon S3 console and click **Create Bucket**. Alternatively, you can use the AWS CLI `mb` command.

- Ensure that you have your AWS account ID. For more information, see [AWS Account Identifiers](#) in the [AWS General Reference](#).
- Ensure that you have your access key ID and secret access key. For more information, see [Access Keys](#) in the [AWS General Reference](#).
- Ensure that you have an X.509 certificate and corresponding private key.
 - If you need to create an X.509 certificate, see [Manage signing certificates \(p. 153\)](#). The X.509 certificate and private key are used to encrypt and decrypt your AMI.

- [China (Beijing)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-cn-north-1.pem` certificate.
- [AWS GovCloud (US-West)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-gov.pem` certificate.
- Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.

Tasks

- [Set up the AMI tools \(p. 151\)](#)
- [Create an AMI from an instance store-backed Amazon Linux instance \(p. 154\)](#)
- [Create an AMI from an instance store-backed Ubuntu instance \(p. 156\)](#)
- [Convert your instance store-backed AMI to an Amazon EBS-backed AMI \(p. 160\)](#)

Set up the AMI tools

You can use the AMI tools to create and manage instance store-backed Linux AMIs. To use the tools, you must install them on your Linux instance. The AMI tools are available as both an RPM and as a .zip file for Linux distributions that don't support RPM.

To set up the AMI tools using the RPM

1. Install Ruby using the package manager for your Linux distribution, such as yum. For example:

```
[ec2-user ~]$ sudo yum install -y ruby
```

2. Download the RPM file using a tool such as wget or curl. For example:

```
[ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.noarch.rpm
```

3. Verify the RPM file's signature using the following command:

```
[ec2-user ~]$ rpm -K ec2-ami-tools.noarch.rpm
```

The command above should indicate that the file's SHA1 and MD5 hashes are OK. If the command indicates that the hashes are NOT OK, use the following command to view the file's Header SHA1 and MD5 hashes:

```
[ec2-user ~]$ rpm -Kv ec2-ami-tools.noarch.rpm
```

Then, compare your file's Header SHA1 and MD5 hashes with the following verified AMI tools hashes to confirm the file's authenticity:

- Header SHA1: a1f662d6f25f69871104e6a62187fa4df508f880
- MD5: 9faff05258064e2f7909b66142de6782

If your file's Header SHA1 and MD5 hashes match the verified AMI tools hashes, continue to the next step.

4. Install the RPM using the following command:

```
[ec2-user ~]$ sudo yum install ec2-ami-tools.noarch.rpm
```

- Verify your AMI tools installation using the [ec2-ami-tools-version \(p. 164\)](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

Note

If you receive a load error such as "cannot load such file -- ec2/amitools/version (LoadError)", complete the next step to add the location of your AMI tools installation to your RUBYLIB path.

- (Optional) If you received an error in the previous step, add the location of your AMI tools installation to your RUBYLIB path.

- Run the following command to determine the paths to add.

```
[ec2-user ~]$ rpm -qil ec2-ami-tools | grep ec2/amitools/version
/usr/lib/ruby/site_ruby/ec2/amitools/version.rb
/usr/lib64/ruby/site_ruby/ec2/amitools/version.rb
```

In the above example, the missing file from the previous load error is located at /usr/lib/ruby/site_ruby and /usr/lib64/ruby/site_ruby.

- Add the locations from the previous step to your RUBYLIB path.

```
[ec2-user ~]$ export RUBYLIB=$RUBYLIB:/usr/lib/ruby/site_ruby:/usr/lib64/ruby/site_ruby
```

- Verify your AMI tools installation using the [ec2-ami-tools-version \(p. 164\)](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

To set up the AMI tools using the .zip file

- Install Ruby and unzip using the package manager for your Linux distribution, such as [apt-get](#). For example:

```
[ec2-user ~]$ sudo apt-get update -y && sudo apt-get install -y ruby unzip
```

- Download the .zip file using a tool such as wget or curl. For example:

```
[ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.zip
```

- Unzip the files into a suitable installation directory, such as /usr/local/ec2.

```
[ec2-user ~]$ sudo mkdir -p /usr/local/ec2
$ sudo unzip ec2-ami-tools.zip -d /usr/local/ec2
```

Notice that the .zip file contains a folder ec2-ami-tools-**x.x.x**, where **x.x.x** is the version number of the tools (for example, ec2-ami-tools-1.5.7).

- Set the EC2_AMITOOL_HOME environment variable to the installation directory for the tools. For example:

```
[ec2-user ~]$ export EC2_AMITOOL_HOME=/usr/local/ec2/ec2-ami-tools-x.x.x
```

- Add the tools to your PATH environment variable. For example:

```
[ec2-user ~]$ export PATH=$EC2_AMITOOL_HOME/bin:$PATH
```

6. You can verify your AMI tools installation using the [ec2-ami-tools-version \(p. 164\)](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

Manage signing certificates

Certain commands in the AMI tools require a signing certificate (also known as X.509 certificate). You must create the certificate and then upload it to AWS. For example, you can use a third-party tool such as OpenSSL to create the certificate.

To create a signing certificate

1. Install and configure OpenSSL.
2. Create a private key using the `openssl genrsa` command and save the output to a `.pem` file. We recommend that you create a 2048- or 4096-bit RSA key.

```
openssl genrsa 2048 > private-key.pem
```

3. Generate a certificate using the `openssl req` command.

```
openssl req -new -x509 -nodes -sha256 -days 365 -key private-key.pem -outform PEM -  
out certificate.pem
```

To upload the certificate to AWS, use the [upload-signing-certificate](#) command.

```
aws iam upload-signing-certificate --user-name user-name --certificate-body file://path/to/certificate.pem
```

To list the certificates for a user, use the [list-signing-certificates](#) command:

```
aws iam list-signing-certificates --user-name user-name
```

To disable or re-enable a signing certificate for a user, use the [update-signing-certificate](#) command. The following command disables the certificate:

```
aws iam update-signing-certificate --certificate-id OFHPLP4ZULTHYPMSYEX704BEXAMPLE --  
status Inactive --user-name user-name
```

To delete a certificate, use the [delete-signing-certificate](#) command:

```
aws iam delete-signing-certificate --user-name user-name --certificate-  
id OFHPLP4ZULTHYPMSYEX704BEXAMPLE
```

Create an AMI from an instance store-backed instance

The following procedures are for creating an instance store-backed AMI from an instance store-backed instance. Before you begin, ensure that you've read the [Prerequisites \(p. 150\)](#).

Topics

- [Create an AMI from an instance store-backed Amazon Linux instance \(p. 154\)](#)

- [Create an AMI from an instance store-backed Ubuntu instance \(p. 156\)](#)

Create an AMI from an instance store-backed Amazon Linux instance

This section describes the creation of an AMI from an Amazon Linux instance. The following procedures may not work for instances running other Linux distributions. For Ubuntu-specific procedures, see [Create an AMI from an instance store-backed Ubuntu instance \(p. 156\)](#).

To prepare to use the AMI tools (HVM instances only)

1. The AMI tools require GRUB Legacy to boot properly. Use the following command to install GRUB:

```
[ec2-user ~]$ sudo yum install -y grub
```

2. Install the partition management packages with the following command:

```
[ec2-user ~]$ sudo yum install -y gdisk kpartx parted
```

To create an AMI from an instance store-backed Amazon Linux instance

This procedure assumes that you have satisfied the prerequisites in [Prerequisites \(p. 150\)](#).

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

- a. Create a temporary directory on your instance for your credentials as follows:

```
[ec2-user ~]$ mkdir /tmp/cert
```

This enables you to exclude your credentials from the created image.

- b. Copy your X.509 certificate and corresponding private key from your computer to the /tmp/cert directory on your instance using a secure copy tool such as [scp \(p. 616\)](#). The `-i my-private-key.pem` option in the following `scp` command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100%   717      0.7KB/s  00:00
cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100%   685      0.7KB/s  00:00
```

Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

2. Prepare the bundle to upload to Amazon S3 by running the [ec2-bundle-vol \(p. 166\)](#) command from inside your instance. Be sure to specify the `-e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*`, `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

Important

By default, the AMI bundling process creates a compressed, encrypted collection of files in the /tmp directory that represents your root volume. If you do not have enough free

disk space in /tmp to store the bundle, you need to specify a different location for the bundle to be stored with the `-d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at /mnt or /media/ephemeral0 that you can use, or you can also [create \(p. 1371\)](#), [attach \(p. 1375\)](#), and [mount \(p. 1382\)](#) a new Amazon Elastic Block Store (Amazon EBS) volume to store the bundle.

- a. You must run the `ec2-bundle-vol` command as root. For most commands, you can use `sudo` to gain elevated permissions, but in this case, you should run `sudo -E su` to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
[root ec2-user]#
```

- b. To create the AMI bundle, run the `ec2-bundle-vol` ([p. 166](#)) command as follows:

```
[root ec2-user]# ec2-bundle-vol -k /tmp/cert/pk-HKZYKTAIG2ECMXY1BH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-HKZYKTAIG2ECMXY1BH3HXV4ZBEXAMPLE.pem -u 123456789012 -r x86_64 -e /tmp/cert --partition gpt
```

Note

For the China (Beijing) and AWS GovCloud (US-West) Regions, use the `--ec2cert` parameter and specify the certificates as per the [prerequisites \(p. 150\)](#).

It can take a few minutes to create the image. When this command completes, your /tmp (or non-default) directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

- c. Exit from the root shell.

```
[root ec2-user]# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see [Block device mappings \(p. 1654\)](#).

- a. Create a backup of your `image.manifest.xml` file.

```
[ec2-user ~]$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

- b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
[ec2-user ~]$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/image.manifest.xml
```

- c. Edit the block device mappings in `image.manifest.xml` with a text editor. The example below shows a new entry for the `ephemeral1` instance store volume.

Note

For a list of excluded files, see [ec2-bundle-vol \(p. 166\)](#).

```
<block_device_mapping>
<mapping>
<virtual>ami</virtual>
```

```
<device>sda</device>
</mapping>
<mapping>
    <virtual>ephemeral0</virtual>
    <device>sdb</device>
</mapping>
<mapping>
    <virtual>ephemeral1</virtual>
    <device>sdc</device>
</mapping>
<mapping>
    <virtual>root</virtual>
    <device>/dev/sda1</device>
</mapping>
</block_device_mapping>
```

- d. Save the `image.manifest.xml` file and exit your text editor.
4. To upload your bundle to Amazon S3, run the [ec2-upload-bundle \(p. 177\)](#) command as follows.

```
[ec2-user ~]$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/  
image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

Important

To register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

```
[ec2-user ~]$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

Important

If you specified a path with the `-d /path/to/bundle/storage` option in [Step 2 \(p. 154\)](#), use that path instead of `/tmp`.

6. To register your AMI, run the `register-image` command as follows.

```
[ec2-user ~]$ aws ec2 register-image --image-location my-s3-  
bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-  
type hvm
```

Important

If you previously specified a Region for the [ec2-upload-bundle \(p. 177\)](#) command, specify that Region again for this command.

Create an AMI from an instance store-backed Ubuntu instance

This section describes the creation of an AMI from an Ubuntu Linux instance with an instance store volume as the root volume. The following procedures may not work for instances running other Linux distributions. For procedures specific to Amazon Linux, see [Create an AMI from an instance store-backed Amazon Linux instance \(p. 154\)](#).

To prepare to use the AMI tools (HVM instances only)

The AMI tools require GRUB Legacy to boot properly. However, Ubuntu is configured to use GRUB 2. You must check to see that your instance uses GRUB Legacy, and if not, you need to install and configure it.

HVM instances also require partitioning tools to be installed for the AMI tools to work properly.

1. GRUB Legacy (version 0.9~~x~~ or less) must be installed on your instance. Check to see if GRUB Legacy is present and install it if necessary.

- a. Check the version of your GRUB installation.

```
ubuntu:~$ grub-install --version
grub-install (GRUB) 1.99-21ubuntu3.10
```

In this example, the GRUB version is greater than 0.9~~x~~, so you must install GRUB Legacy. Proceed to [Step 1.b \(p. 157\)](#). If GRUB Legacy is already present, you can skip to [Step 2 \(p. 157\)](#).

- b. Install the grub package using the following command.

```
ubuntu:~$ sudo apt-get install -y grub
```

2. Install the following partition management packages using the package manager for your distribution.

- gdisk (some distributions may call this package gptfdisk instead)
- kpartx
- parted

Use the following command.

```
ubuntu:~$ sudo apt-get install -y gdisk kpartx parted
```

3. Check the kernel parameters for your instance.

```
ubuntu:~$ cat /proc/cmdline
BOOT_IMAGE=/boot/vmlinuz-3.2.0-54-virtual root=UUID=4f392932-ed93-4f8f-
aee7-72bc5bb6ca9d ro console=ttyS0 xen_emul_unplug=unnecessary
```

Note the options following the kernel and root device parameters: `ro`, `console=ttyS0`, and `xen_emul_unplug=unnecessary`. Your options may differ.

4. Check the kernel entries in `/boot/grub/menu.lst`.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel  /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=hvc0
kernel  /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
kernel  /boot/memtest86+.bin
```

Note that the `console` parameter is pointing to `hvc0` instead of `ttyS0` and that the `xen_emul_unplug=unnecessary` parameter is missing. Again, your options may differ.

5. Edit the `/boot/grub/menu.lst` file with your favorite text editor (such as `vim` or `nano`) to change the `console` and add the parameters you identified earlier to the boot entries.

```
title      Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual
root      (hd0)
kernel    /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs
          ro console=ttyS0 xen_emul_unplug=unnecessary
initrd   /boot/initrd.img-3.2.0-54-virtual

title      Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual (recovery mode)
root      (hd0)
```

```
kernel      /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro
single console=ttyS0 xen_emul_unplug=unnecessary
initrd     /boot/initrd.img-3.2.0-54-virtual

title       Ubuntu 12.04.3 LTS, memtest86+
root        (hd0)
kernel     /boot/memtest86+.bin
```

- Verify that your kernel entries now contain the correct parameters.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel  /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=ttyS0
xen_emul_unplug=unnecessary
kernel  /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
console=ttyS0 xen_emul_unplug=unnecessary
kernel  /boot/memtest86+.bin
```

- [For Ubuntu 14.04 and later only] Starting with Ubuntu 14.04, instance store backed Ubuntu AMIs use a GPT partition table and a separate EFI partition mounted at /boot/efi. The **ec2-bundle-vol** command will not bundle this boot partition, so you need to comment out the /etc/fstab entry for the EFI partition as shown in the following example.

```
LABEL=cloudimg-rootfs   /          ext4    defaults        0 0
#LABEL=UEFI            /boot/efi    vfat    defaults        0 0
/dev/xvdb             /mnt      auto    defaults,nobootwait,comment=cloudconfig 0      2
```

To create an AMI from an instance store-backed Ubuntu instance

This procedure assumes that you have satisfied the prerequisites in [Prerequisites \(p. 150\)](#).

- Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

- Create a temporary directory on your instance for your credentials as follows:

```
ubuntu:~$ mkdir /tmp/cert
```

This enables you to exclude your credentials from the created image.

- Copy your X.509 certificate and private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as [scp \(p. 616\)](#). The **-i my-private-key.pem** option in the following **scp** command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /
path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 717      0.7KB/s  00:00
cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 685      0.7KB/s  00:00
```

Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

- Prepare the bundle to upload to Amazon S3 by running the [ec2-bundle-vol \(p. 166\)](#) command from your instance. Be sure to specify the **-e** option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include ***.sw, *.swo, *.swp, *.pem, *.priv, *id_rsa*, *id_dsa*, *.gpg, *.jks,**

`*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

Important

By default, the AMI bundling process creates a compressed, encrypted collection of files in the `/tmp` directory that represents your root volume. If you do not have enough free disk space in `/tmp` to store the bundle, you need to specify a different location for the bundle to be stored with the `-d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at `/mnt` or `/media/ephemeral0` that you can use, or you can also [create \(p. 1371\)](#), [attach \(p. 1375\)](#), and [mount \(p. 1382\)](#) a new Amazon Elastic Block Store (Amazon EBS) volume to store the bundle.

- a. You must run the `ec2-bundle-vol` command needs as root. For most commands, you can use `sudo` to gain elevated permissions, but in this case, you should run `sudo -E su` to keep your environment variables.

```
ubuntu:~$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
root@ubuntu:#
```

- b. To create the AMI bundle, run the [ec2-bundle-vol \(p. 166\)](#) command as follows.

```
root@ubuntu:# ec2-bundle-vol -k /tmp/cert/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem  
-c /tmp/cert/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u your_aws_account_id -r  
x86_64 -e /tmp/cert --partition gpt
```

Important

For Ubuntu 14.04 and later HVM instances, add the `--partition mbr` flag to bundle the boot instructions properly; otherwise, your newly-created AMI will not boot.

It can take a few minutes to create the image. When this command completes, your `tmp` directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

- c. Exit from the root shell.

```
root@ubuntu:# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see [Block device mappings \(p. 1654\)](#).

- a. Create a backup of your `image.manifest.xml` file.

```
ubuntu:~$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

- b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
ubuntu:~$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/  
image.manifest.xml
```

- c. Edit the block device mappings in `image.manifest.xml` with a text editor. The example below shows a new entry for the `ephemeral1` instance store volume.

```
<block_device_mapping>  
<mapping>
```

```
<virtual>ami</virtual>
<device>sda</device>
</mapping>
<mapping>
<virtual>ephemeral0</virtual>
<device>sdb</device>
</mapping>
<mapping>
<virtual>ephemeral1</virtual>
<device>sdc</device>
</mapping>
<mapping>
<virtual>root</virtual>
<device>/dev/sda1</device>
</mapping>
</block_device_mapping>
```

- d. Save the `image.manifest.xml` file and exit your text editor.
4. To upload your bundle to Amazon S3, run the [ec2-upload-bundle \(p. 177\)](#) command as follows.

```
ubuntu:~$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/
image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

Important

If you intend to register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

```
ubuntu:~$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

Important

If you specified a path with the `-d /path/to/bundle/storage` option in [Step 2 \(p. 158\)](#), use that same path below, instead of `/tmp`.

6. To register your AMI, run the `register-image` AWS CLI command as follows.

```
ubuntu:~$ aws ec2 register-image --image-location my-s3-
bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-
type hvm
```

Important

If you previously specified a Region for the [ec2-upload-bundle \(p. 177\)](#) command, specify that Region again for this command.

7. [Ubuntu 14.04 and later] Uncomment the EFI entry in `/etc/fstab`; otherwise, your running instance will not be able to reboot.

Convert your instance store-backed AMI to an Amazon EBS-backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

Important

You can't convert an instance store-backed Windows AMI to an Amazon EBS-backed Windows AMI and you cannot convert an AMI that you do not own.

To convert an instance store-backed AMI to an Amazon EBS-backed AMI

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#). Amazon Linux instances have the AWS CLI and AMI tools pre-installed.
2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.
 - a. Create a temporary directory on your instance for your X.509 private key as follows:

```
[ec2-user ~]$ mkdir /tmp/cert
```

- b. Copy your X.509 private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as [scp \(p. 616\)](#). The *my-private-key* parameter in the following command is the private key you use to connect to your instance with SSH. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /  
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-  
user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/  
pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 717 0.7KB/s 00:00
```

3. Set environment variables for your AWS access key and secret key.

```
[ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id  
[ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
```

4. Prepare an Amazon Elastic Block Store (Amazon EBS) volume for your new AMI.

- a. Create an empty EBS volume in the same Availability Zone as your instance using the [create-volume](#) command. Note the volume ID in the command output.

Important

This EBS volume must be the same size or larger than the original instance store root volume.

```
[ec2-user ~]$ aws ec2 create-volume --size 10 --region us-west-2 --availability-zone us-west-2b
```

- b. Attach the volume to your Amazon EBS-backed instance using the [attach-volume](#) command.

```
[ec2-user ~]$ aws ec2 attach-volume --volume-id volume_id --instance-id instance_id  
--device /dev/sdb --region us-west-2
```

5. Create a folder for your bundle.

```
[ec2-user ~]$ mkdir /tmp/bundle
```

6. Download the bundle for your instance store-based AMI to /tmp/bundle using the [ec2-download-bundle \(p. 172\)](#) command.

```
[ec2-user ~]$ ec2-download-bundle -b my-s3-bucket/bundle_folder/bundle_name -m  
image.manifest.xml -a $AWS_ACCESS_KEY_ID -s $AWS_SECRET_ACCESS_KEY --privatekey /path/  
to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d /tmp/bundle
```

7. Reconstitute the image file from the bundle using the [ec2-unbundle \(p. 176\)](#) command.

- a. Change directories to the bundle folder.

```
[ec2-user ~]$ cd /tmp/bundle/
```

- b. Run the [ec2-unbundle \(p. 176\)](#) command.

```
[ec2-user bundle]$ ec2-unbundle -m image.manifest.xml --privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem
```

8. Copy the files from the unbundled image to the new EBS volume.

```
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Probe the volume for any new partitions that were unbundled.

```
[ec2-user bundle]$ sudo partprobe /dev/sdb1
```

10. List the block devices to find the device name to mount.

```
[ec2-user bundle]$ lsblk
NAME      MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
/dev/sda    202:0   0   8G  0 disk
##/dev/sda1 202:1   0   8G  0 part /
/dev/sdb    202:80  0  10G  0 disk
##/dev/sdb1 202:81  0  10G  0 part
```

In this example, the partition to mount is /dev/sdb1, but your device name will likely be different. If your volume is not partitioned, then the device to mount will be similar to /dev/sdb (without a device partition trailing digit).

11. Create a mount point for the new EBS volume and mount the volume.

```
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb1 /mnt/ebs
```

12. Open the /etc/fstab file on the EBS volume with your favorite text editor (such as **vim** or **nano**) and remove any entries for instance store (ephemeral) volumes. Because the EBS volume is mounted on /mnt/ebs, the fstab file is located at /mnt/ebs/etc/fstab.

```
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab
#
LABEL=/      /          ext4      defaults,noatime 1 1
tmpfs       /dev/shm    tmpfs     defaults        0 0
devpts      /dev/pts    devpts    gid=5,mode=620 0 0
sysfs       /sys        sysfs    defaults        0 0
proc        /proc       proc     defaults        0 0
/dev/sdb    /media/ephemeral0  auto    defaults,comment=cloudconfig 0
2
```

In this example, the last line should be removed.

13. Unmount the volume and detach it from the instance.

```
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ aws ec2 detach-volume --volume-id volume_id --region us-west-2
```

14. Create an AMI from the new EBS volume as follows.

- a. Create a snapshot of the new EBS volume.

```
[ec2-user bundle]$ aws ec2 create-snapshot --region us-west-2 --description "your_snapshot_description" --volume-id volume_id
```

- b. Check to see that your snapshot is complete.

```
[ec2-user bundle]$ aws ec2 describe-snapshots --region us-west-2 --snapshot-id snapshot_id
```

- c. Identify the processor architecture, virtualization type, and the kernel image (aki) used on the original AMI with the **describe-images** command. You need the AMI ID of the original instance store-backed AMI for this step.

```
[ec2-user bundle]$ aws ec2 describe-images --region us-west-2 --image-id ami_id --output text
IMAGES x86_64 amazon/amzn-ami-pv-2013.09.2.x86_64-s3 ami-8ef297be amazon available
public machine aki-fc8f11cc instance-store paravirtual xen
```

In this example, the architecture is x86_64 and the kernel image ID is aki-fc8f11cc. Use these values in the following step. If the output of the above command also lists an ari ID, take note of that as well.

- d. Register your new AMI with the snapshot ID of your new EBS volume and the values from the previous step. If the previous command output listed an ari ID, include that in the following command with --ramdisk-id *ari_id*.

```
[ec2-user bundle]$ aws ec2 register-image --region us-west-2 --name your_new_ami_name --block-device-mappings DeviceName=device-name,Ebs={SnapshotId=snapshot_id} --virtualization-type paravirtual --architecture x86_64 --kernel-id aki-fc8f11cc --root-device-name device-name
```

15. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the EBS volume that you created for this procedure.

```
aws ec2 delete-volume --volume-id volume_id
```

AMI tools reference

You can use the AMI tools commands to create and manage instance store-backed Linux AMIs. To set up the tools, see [Set up the AMI tools \(p. 151\)](#).

[ec2-ami-tools-version](#)

Description

Describes the version of the AMI tools.

Syntax

ec2-ami-tools-version

Output

The version information.

Example

This example command displays the version information for the AMI tools that you're using.

```
[ec2-user ~]$ ec2-ami-tools-version
1.5.2 20071010
```

[ec2-bundle-image](#)

Description

Creates an instance store-backed Linux AMI from an operating system image created in a loopback file.

Syntax

```
ec2-bundle-image -c path -k path -u account -i path [-d path] [--ec2cert path]
[-r architecture] [--productcodes code1,code2,...] [-B mapping] [-p prefix]
```

Options

-c, --cert *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey *path*

The path to a PEM-encoded RSA key file. You'll need to specify this key to unbundle this bundle, so keep it in a safe place. Note that the key doesn't have to be registered to your AWS account.

Required: Yes

-u, --user *account*

The user's AWS account ID, without dashes.

Required: Yes

-i, --image *path*

The path to the image to bundle.

Required: Yes

-d, --destination *path*

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in [Set up the AMI tools \(p. 151\)](#), the certificates are located at \$EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch *architecture*

Image architecture. If you don't provide the architecture on the command line, you'll be prompted for it when bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- ami—The root file system device, as seen by the instance
- root—The root file system device, as seen by the kernel
- swap—The swap device, as seen by the instance
- ephemeralN—The Nth instance store volume

Required: No

-p, --prefix *prefix*

The filename prefix for bundled AMI files.

Default: The name of the image file. For example, if the image path is /var/spool/my-image/version-2/debian.img, then the default prefix is debian.img.

Required: No

--kernel *kernel_id*

Deprecated. Use [register-image](#) to set the kernel.

Required: No

--ramdisk *ramdisk_id*

Deprecated. Use [register-image](#) to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example creates a bundled AMI from an operating system image that was created in a loopback file.

```
[ec2-user ~]$ ec2-bundle-image -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -i image.img -d bundled/ -r x86_64

ec2-bundle-vol

Description

Creates an instance store-backed Linux AMI by compressing, encrypting, and signing a copy of the root device volume for the instance.

Amazon EC2 attempts to inherit product codes, kernel settings, RAM disk settings, and block device mappings from the instance.

By default, the bundle process excludes files that might contain sensitive information. These files include *.sw, *.swo, *.swp, *.pem, *.priv, *id_rsa*, *id_dsa* *.gpg, *.jks, */.ssh/authorized_keys, and */.bash_history. To include all of these files, use the --no-filter option. To include some of these files, use the --include option.

For more information, see [Create an instance store-backed Linux AMI \(p. 149\)](#).

Syntax

```
ec2-bundle-vol -c path -k path -u account [-d path] [--ec2cert path] [-r architecture] [--productcodes code1,code2,...] [-B mapping] [--all] [-e directory1,directory2,...] [-i file1,file2,...] [--no-filter] [-p prefix] [-s size] [--[no-]inherit] [-v volume] [-P type] [-S script] [--fstab path] [--generate-fstab] [--grub-config path]
```

Options

-c, --cert *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey *path*

The path to the user's PEM-encoded RSA key file.

Required: Yes

-u, --user *account*

The user's AWS account ID, without dashes.

Required: Yes

-d, --destination *destination*

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in [Set up the AMI tools \(p. 151\)](#), the certificates are located at \$EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch *architecture*

The image architecture. If you don't provide this on the command line, you'll be prompted to provide it when the bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- ami—The root file system device, as seen by the instance

- **root**—The root file system device, as seen by the kernel
- **swap**—The swap device, as seen by the instance
- **ephemeralN**—The Nth instance store volume

Required: No

-a, --all

Bundle all directories, including those on remotely mounted file systems.

Required: No

-e, --exclude directory1,directory2,...

A list of absolute directory paths and files to exclude from the bundle operation. This parameter overrides the **--all** option. When exclude is specified, the directories and subdirectories listed with the parameter will not be bundled with the volume.

Required: No

-i, --include file1,file2,...

A list of files to include in the bundle operation. The specified files would otherwise be excluded from the AMI because they might contain sensitive information.

Required: No

--no-filter

If specified, we won't exclude files from the AMI because they might contain sensitive information.

Required: No

-p, --prefix prefix

The file name prefix for bundled AMI files.

Default: `image`

Required: No

-s, --size size

The size, in MB (1024 * 1024 bytes), of the image file to create. The maximum size is 10240 MB.

Default: 10240

Required: No

--[no-]inherit

Indicates whether the image should inherit the instance's metadata (the default is to inherit). Bundling fails if you enable **--inherit** but the instance metadata is not accessible.

Required: No

-v, --volume volume

The absolute path to the mounted volume from which to create the bundle.

Default: The root directory (/)

Required: No

-P, --partition type

Indicates whether the disk image should use a partition table. If you don't specify a partition table type, the default is the type used on the parent block device of the volume, if applicable, otherwise the default is gpt.

Valid values: mbr | gpt | none

Required: No

-S, --script script

A customization script to be run right before bundling. The script must expect a single argument, the mount point of the volume.

Required: No

--fstab path

The path to the fstab to bundle into the image. If this is not specified, Amazon EC2 bundles /etc/fstab.

Required: No

--generate-fstab

Bundles the volume using an Amazon EC2-provided fstab.

Required: No

--grub-config

The path to an alternate grub configuration file to bundle into the image. By default, ec2-bundle-vol expects either /boot/grub/menu.lst or /boot/grub/grub.conf to exist on the cloned image. This option allows you to specify a path to an alternative grub configuration file, which will then be copied over the defaults (if present).

Required: No

--kernel kernel_id

Deprecated. Use [register-image](#) to set the kernel.

Required: No

--ramdiskramdisk_id

Deprecated. Use [register-image](#) to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling.

Example

This example creates a bundled AMI by compressing, encrypting and signing a snapshot of the local machine's root file system.

```
[ec2-user ~]$ ec2-bundle-vol -d /mnt -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -r x86_64

ec2-delete-bundle

Description

Deletes the specified bundle from Amazon S3 storage. After you delete a bundle, you can't launch instances from the corresponding AMI.

Syntax

```
ec2-delete-bundle -b bucket -a access_key_id -s secret_access_key [-t token]  
[--url url] [--region region] [--sigv version] [-m path] [-p prefix] [--clear]  
[--retry] [-y]
```

Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket containing the bundled AMI, followed by an optional '/'-delimited path prefix

Required: Yes

-a, --access-key *access_key_id*

The AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

The AWS secret access key.

Required: Yes

-t, --delegation-token *token*

The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#).

Required: Only when you are using temporary security credentials.

Default: The value of the `AWS_DELEGATION_TOKEN` environment variable (if set).

--region *region*

The Region to use in the request signature.

Default: `us-east-1`

Required: Required if using signature version 4

--sigvversion

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

-m, --manifestpath

The path to the manifest file.

Required: You must specify `--prefix` or `--manifest`.

-p, --prefix *prefix*

The bundled AMI filename prefix. Provide the entire prefix. For example, if the prefix is `image.img`, use `-p image.img` and not `-p image`.

Required: You must specify `--prefix` or `--manifest`.

--clear

Deletes the Amazon S3 bucket if it's empty after deleting the specified bundle.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

-y, --yes

Automatically assumes the answer to all prompts is yes.

Required: No

Output

Amazon EC2 displays status messages indicating the stages and status of the delete process.

Example

This example deletes a bundle from Amazon S3.

```

ec2-download-bundle

Description

Downloads the specified instance store-backed Linux AMIs from Amazon S3 storage.

Syntax

```
ec2-download-bundle -b bucket -a access_key_id -s secret_access_key -k path  
[--url url] [--region region] [--sigv version] [-m file] [-p prefix] [-d directory] [--retry]
```

Options

-b, --bucket bucket

The name of the Amazon S3 bucket where the bundle is located, followed by an optional '/'- delimited path prefix.

Required: Yes

-a, --access-key access_key_id

The AWS access key ID.

Required: Yes

-s, --secret-key secret_access_key

The AWS secret access key.

Required: Yes

-k, --privatekey *path*

The private key used to decrypt the manifest.

Required: Yes

--url *url*

The Amazon S3 service URL.

Default: <https://s3.amazonaws.com/>

Required: No

--region *region*

The Region to use in the request signature.

Default: us-east-1

Required: Required if using signature version 4

--sigv *version*

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

-m, --manifest *file*

The name of the manifest file (without the path). We recommend that you specify either the manifest (-m) or a prefix (-p).

Required: No

-p, --prefix *prefix*

The filename prefix for the bundled AMI files.

Default: image

Required: No

-d, --directory *directory*

The directory where the downloaded bundle is saved. The directory must exist.

Default: The current working directory.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

Output

Status messages indicating the various stages of the download process are displayed.

Example

This example creates the bundled directory (using the Linux **mkdir** command) and downloads the bundle from the **DOC-EXAMPLE-BUCKET1** Amazon S3 bucket.

```
[ec2-user ~]$ mkdir bundled

ec2-migrate-manifest

Description

Modifies an instance store-backed Linux AMI (for example, its certificate, kernel, and RAM disk) so that it supports a different Region.

Syntax

```
ec2-migrate-manifest -c path -k path -m path {(-a access_key_id -s secret_access_key --region region) | (--no-mapping)} [--ec2cert ec2_cert_path] [--kernel kernel_id] [--ramdisk ramdisk_id]
```

Options

-c, --cert path

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey path

The path to the user's PEM-encoded RSA key file.

Required: Yes

--manifest path

The path to the manifest file.

Required: Yes

`-a, --access-key access_key_id`

The AWS access key ID.

Required: Required if using automatic mapping.

`-s, --secret-key secret_access_key`

The AWS secret access key.

Required: Required if using automatic mapping.

`--region region`

The Region to look up in the mapping file.

Required: Required if using automatic mapping.

`--no-mapping`

Disables automatic mapping of kernels and RAM disks.

During migration, Amazon EC2 replaces the kernel and RAM disk in the manifest file with a kernel and RAM disk designed for the destination region. Unless the `--no-mapping` parameter is given, `ec2-migrate-bundle` might use the `DescribeRegions` and `DescribeImages` operations to perform automated mappings.

Required: Required if you're not providing the `-a`, `-s`, and `--region` options used for automatic mapping.

`--ec2cert path`

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The `us-gov-west-1` and `cn-north-1` Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at `/opt/aws/amitools/ec2/etc/ec2/amitools/`. If you installed the AMI tools from the ZIP file in [Set up the AMI tools \(p. 151\)](#), the certificates are located at `$EC2_AMITOOL_HOME/etc/ec2/amitools/`.

Required: Only for the `us-gov-west-1` and `cn-north-1` Regions.

`--kernel kernel_id`

The ID of the kernel to select.

Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see [User provided kernels \(p. 229\)](#).

Required: No

`--ramdisk ramdisk_id`

The ID of the RAM disk to select.

Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see [User provided kernels \(p. 229\)](#).

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example copies the AMI specified in the `my-ami.manifest.xml` manifest from the US to the EU.

```
[ec2-user ~]$ ec2-migrate-manifest --manifest my-ami.manifest.xml --cert cert-HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CLO.pem --privatekey pk-HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CLO.pem --region eu-west-1

Backing up manifest...
Successfully migrated my-ami.manifest.xml It is now suitable for use in eu-west-1.
```

ec2-unbundle

Description

Re-creates the bundle from an instance store-backed Linux AMI.

Syntax

```
ec2-unbundle -k path -m path [-s source_directory] [-d destination_directory]
```

Options

-k, --privatekey *path*

The path to your PEM-encoded RSA key file.

Required: Yes

-m, --manifest *path*

The path to the manifest file.

Required: Yes

-s, --source *source_directory*

The directory containing the bundle.

Default: The current directory.

Required: No

-d, --destination *destination_directory*

The directory in which to unbundle the AMI. The destination directory must exist.

Default: The current directory.

Required: No

Example

This Linux and UNIX example unbundles the AMI specified in the `image.manifest.xml` file.

```
[ec2-user ~]$ mkdir unbundled
$ ec2-unbundle -m mybundle/image.manifest.xml -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -s mybundle -d unbundled
```

```
$ ls -l unbundled
total 1025008
-rw-r--r-- 1 root root 1048578048 Aug 25 23:46 image.img
```

Output

Status messages indicating the various stages of the unbundling process are displayed.

ec2-upload-bundle

Description

Uploads the bundle for an instance store-backed Linux AMI to Amazon S3 and sets the appropriate access control lists (ACLs) on the uploaded objects. For more information, see [Create an instance store-backed Linux AMI \(p. 149\)](#).

Note

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see [Controlling ownership of uploaded objects using S3 Object Ownership](#).

Syntax

```
ec2-upload-bundle -b bucket -a access_key_id -s secret_access_key [-t token] -m
path [--url url] [--region region] [--sigv version] [--acl acl] [-d directory]
[--part part] [--retry] [--skipmanifest]
```

Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket in which to store the bundle, followed by an optional '/'- delimited path prefix. If the bucket doesn't exist, it's created if the bucket name is available.

Required: Yes

-a, --access-key *access_key_id*

Your AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

Your AWS secret access key.

Required: Yes

-t, --delegation-token *token*

The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#).

Required: Only when you are using temporary security credentials.

Default: The value of the `AWS_DELEGATION_TOKEN` environment variable (if set).

-m, --manifest *path*

The path to the manifest file. The manifest file is created during the bundling process and can be found in the directory containing the bundle.

Required: Yes

--url *url*

Deprecated. Use the --region option instead unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.

The Amazon S3 endpoint service URL.

Default: <https://s3.amazonaws.com/>

Required: No

--region *region*

The Region to use in the request signature for the destination S3 bucket.

- If the bucket doesn't exist and you don't specify a Region, the tool creates the bucket without a location constraint (in us-east-1).
- If the bucket doesn't exist and you specify a Region, the tool creates the bucket in the specified Region.
- If the bucket exists and you don't specify a Region, the tool uses the bucket's location.
- If the bucket exists and you specify us-east-1 as the Region, the tool uses the bucket's actual location without any error message, any existing matching files are over-written.
- If the bucket exists and you specify a Region (other than us-east-1) that doesn't match the bucket's actual location, the tool exits with an error.

If your bucket is constrained to the EU location (and not eu-west-1), use the --location flag instead. The --location flag is the only way to target that specific location restraint.

Default: us-east-1

Required: Required if using signature version 4

--sigv *version*

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

--acl *acl*

The access control list policy of the bundled image.

Valid values: public-read | aws-exec-read

Default: aws-exec-read

Required: No

-d, --directory *directory*

The directory containing the bundled AMI parts.

Default: The directory containing the manifest file (see the -m option).

Required: No

--part *part*

Starts uploading the specified part and all subsequent parts. For example, --part 04.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

--skipmanifest

Does not upload the manifest.

Required: No

--location *location*

Deprecated. Use the --region option instead, unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.

The location constraint of the destination Amazon S3 bucket. If the bucket exists and you specify a location that doesn't match the bucket's actual location, the tool exits with an error. If the bucket exists and you don't specify a location, the tool uses the bucket's location. If the bucket doesn't exist and you specify a location, the tool creates the bucket in the specified location. If the bucket doesn't exist and you don't specify a location, the tool creates the bucket without a location constraint (in us-east-1).

Default: If --region is specified, the location is set to that specified Region. If --region is not specified, the location defaults to us-east-1.

Required: No

Output

Amazon EC2 displays status messages that indicate the stages and status of the upload process.

Example

Common options for AMI tools

Most of the AMI tools accept the following optional parameters.

--help, -h

Displays the help message.

--version

Displays the version and copyright notice.

--manual

Displays the manual entry.

--batch

Runs in batch mode, suppressing interactive prompts.

--debug

Displays information that can be useful when troubleshooting problems.

Copy an AMI

You can copy an Amazon Machine Image (AMI) within or across AWS Regions. You can copy both Amazon EBS-backed AMIs and instance-store-backed AMIs. You can copy AMIs with encrypted snapshots and also change encryption status during the copy process. You can copy AMIs that are shared with you.

Copying a source AMI results in an identical but distinct target AMI with its own unique identifier. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an Amazon EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

There are no charges for copying an AMI. However, standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

Considerations

- You can use IAM policies to grant or deny users permissions to copy AMIs. Resource-level permissions specified for the `CopyImage` action apply only to the new AMI. You cannot specify resource-level permissions for the source AMI.
- AWS does not copy launch permissions, user-defined tags, or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions, user-defined tags, and Amazon S3 bucket permissions to the new AMI.
- If you are using an AWS Marketplace AMI, or an AMI that was directly or indirectly derived from an AWS Marketplace AMI, you cannot copy it across accounts. Instead, launch an EC2 instance using the AWS Marketplace AMI and then create an AMI from the instance. For more information, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#).

Permissions for copying an instance store-backed AMI

If you use an IAM user to copy an instance store-backed AMI, the user must have the following Amazon S3 permissions: `s3:CreateBucket`, `s3:GetBucketAcl`, `s3>ListAllMyBuckets`, `s3:GetObject`, `s3:PutObject`, and `s3:PutObjectAcl`.

The following example policy allows the user to copy the AMI source in the specified bucket to the specified Region.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3>ListAllMyBuckets",  
            "Resource": [  
                "arn:aws:s3:::*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": "s3:GetObject",  
            "Resource": [  
                "arn:aws:s3:::ami-source-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>CreateBucket",  
                "s3:GetBucketAcl",  
                "s3:PutObjectAcl",  
                "s3:PutObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amis-for-123456789012-in-us-east-1*"  
            ]  
        }  
    ]  
}
```

To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>, in the navigation pane choose **AMIs**, and locate the bucket name in the **Source** column.

Note

The `s3:CreateBucket` permission is only needed the first time that the IAM user copies an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

Copy an AMI

You can copy an AMI using the AWS Management Console, the AWS Command Line Interface or SDKs, or the Amazon EC2 API, all of which support the [CopyImage](#) action.

Prerequisite

Create or obtain an AMI backed by an Amazon EBS snapshot. Note that you can use the Amazon EC2 console to search a wide variety of AMIs provided by AWS. For more information, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#) and [Finding an AMI](#).

New console

To copy an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console navigation bar, select the Region that contains the AMI.
3. In the navigation pane, choose **Images, AMIs** to display the list of AMIs available to you in the Region.
4. Select the AMI to copy and choose **Actions, Copy AMI**.
5. On the **Copy AMI** page, specify the following information:
 - **AMI copy name:** A name for the new AMI. You can include operating system information in the name, as we do not provide this information when displaying details about the AMI.
 - **AMI copy description:** By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
 - **Destination Region:** The Region in which to copy the AMI. For more information, see [Cross-Region copying \(p. 184\)](#).
 - **Encrypt EBS snapshots of AMI copy:** Select this check box to encrypt the target snapshots, or to re-encrypt them using a different key. If you have enabled [encryption by default \(p. 1545\)](#), the **Encrypt EBS snapshots of AMI copy** check box is selected and cannot be cleared. For more information, see [Encryption and copying \(p. 185\)](#).
 - **KMS key:** The KMS key to used to encrypt the target snapshots.
6. Choose **Copy AMI**.

The initial status of the new AMI is **Pending**. The AMI copy operation is complete when the status is **Available**.

Old console

To copy an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console navigation bar, select the Region that contains the AMI. In the navigation pane, choose **Images, AMIs** to display the list of AMIs available to you in the Region.
3. Select the AMI to copy and choose **Actions, Copy AMI**.
4. In the **Copy AMI** dialog box, specify the following information and then choose **Copy AMI**:
 - **Destination region:** The Region in which to copy the AMI. For more information, see [Cross-Region copying \(p. 184\)](#).
 - **Name:** A name for the new AMI. You can include operating system information in the name, as we do not provide this information when displaying details about the AMI.

- **Description:** By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
 - **Encryption:** Select this field to encrypt the target snapshots, or to re-encrypt them using a different key. If you have enabled [encryption by default \(p. 1545\)](#), the **Encryption** option is set and cannot be unset. For more information, see [Encryption and copying \(p. 185\)](#).
 - **KMS Key:** The KMS key to used to encrypt the target snapshots.
5. We display a confirmation page to let you know that the copy operation has been initiated and to provide you with the ID of the new AMI.

To check on the progress of the copy operation immediately, follow the provided link. To check on the progress later, choose **Done**, and then when you are ready, use the navigation bar to switch to the target Region (if applicable) and locate your AMI in the list of AMIs.

The initial status of the target AMI is **pending** and the operation is complete when the status is **available**.

To copy an AMI using the AWS CLI

You can copy an AMI using the [copy-image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using either the `--region` parameter or an environment variable. For more information, see [Configuring the AWS Command Line Interface](#).

When you encrypt a target snapshot during copying, you must specify these additional parameters: `--encrypted` and `--kms-key-id`.

To copy an AMI using the Tools for Windows PowerShell

You can copy an AMI using the [Copy-EC2Image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `-SourceRegion` parameter. You can specify the destination Region using either the `-Region` parameter or the `Set-AWSDefaultRegion` command. For more information, see [Specifying AWS Regions](#).

When you encrypt a target snapshot during copying, you must specify these additional parameters: `-Encrypted` and `-KmsKeyId`.

Stop a pending AMI copy operation

You can stop a pending AMI copy as follows.

New console

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying and choose **Actions, Deregister AMI**.
5. When asked for confirmation, choose **Deregister AMI**.

Old console

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying and choose **Actions, Deregister**.
5. When asked for confirmation, choose **Continue**.

To stop an AMI copy operation using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

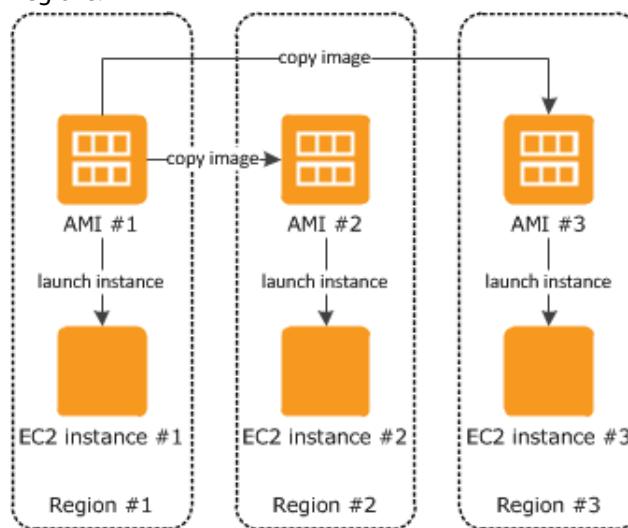

- [deregister-image](#) (AWS CLI)
- [Unregister-EC2Image](#) (AWS Tools for Windows PowerShell)

Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- **Consistent global deployment:** Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- **Scalability:** You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- **Performance:** You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- **High availability:** You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relations among a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.

When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: `amis-for-account-in-region-hash`. For example: `amis-for-123456789012-in-us-east-2-yhjmxvp6`.

Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region may still use the resources from the source Region, which can impact performance and cost.

Limits

- Destination Regions are limited to 100 concurrent AMI copies.
- You cannot copy a paravirtual (PV) AMI to a Region that does not support PV AMIs. For more information, see [Linux AMI virtualization types \(p. 108\)](#).

Cross-account copying

You can share an AMI with another AWS account. Sharing an AMI does not affect the ownership of the AMI. The owning account is charged for the storage in the Region. For more information, see [Share an AMI with specific AWS accounts \(p. 133\)](#).

If you copy an AMI that has been shared with your account, you are the owner of the target AMI in your account. The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees, and you are charged for the storage of the target AMI in the destination Region.

Resource Permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI, either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you as well.

Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

Scenario	Description	Supported
1	Unencrypted-to-unencrypted	Yes
2	Encrypted-to-encrypted	Yes
3	Unencrypted-to-encrypted	Yes
4	Encrypted-to-unencrypted	No

Note

Encrypting during the `CopyImage` action applies only to Amazon EBS-backed AMIs. Because an instance store-backed AMI does not rely on snapshots, you cannot use copying to change its encryption status.

By default (i.e., without specifying encryption parameters), the backing snapshot of an AMI is copied with its original encryption status. Copying an AMI backed by an unencrypted snapshot results in an identical

target snapshot that is also unencrypted. If the source AMI is backed by an encrypted snapshot, copying it results in an identical target snapshot that is encrypted by the same AWS KMS key. Copying an AMI backed by multiple snapshots preserves, by default, the source encryption status in each target snapshot.

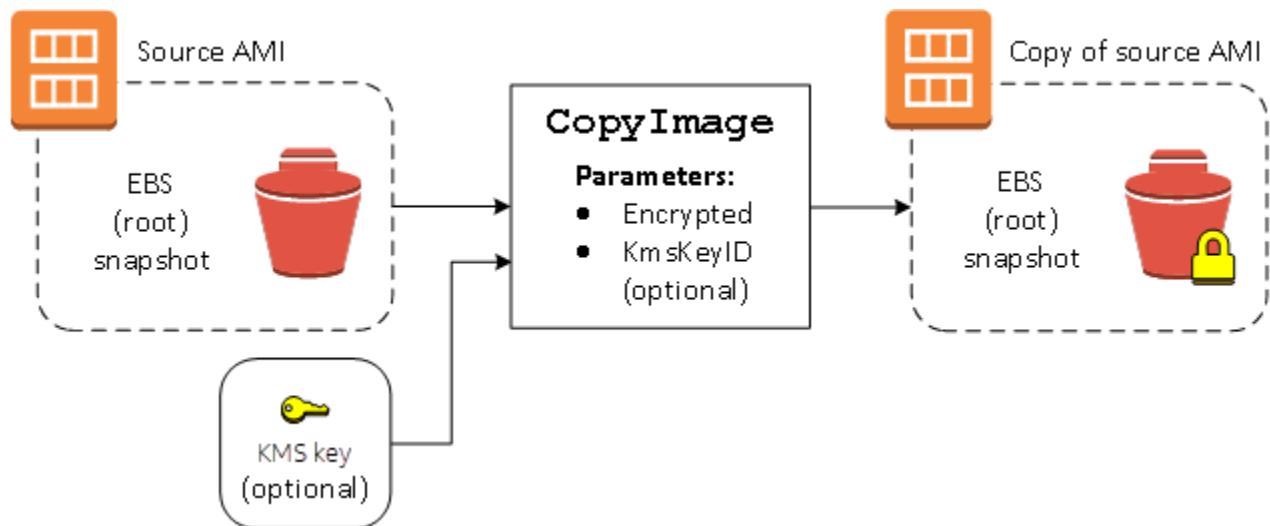

If you specify encryption parameters while copying an AMI, you can encrypt or re-encrypt its backing snapshots. The following example shows a non-default case that supplies encryption parameters to the `CopyImage` action in order to change the target AMI's encryption state.

Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling [encryption by default \(p. 1545\)](#) has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.

Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see [Use encryption with EBS-backed AMIs \(p. 203\)](#).

Store and restore an AMI using S3

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3 buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are `CreateStoreImageTask`, `DescribeStoreImageTasks`, and `CreateRestoreImageTask`.

`CopyImage` is the recommended API to use for copying AMIs *within* an AWS [partition](#). However, `CopyImage` can't copy an AMI to *another* partition.

Warning

Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

Use cases

Use the store and restore APIs to do the following:

- [Copy an AMI from one AWS partition to another AWS partition \(p. 187\)](#)
- [Make archival copies of AMIs \(p. 188\)](#)

Copy an AMI from one AWS partition to another AWS partition

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the `us-east-2` Region to the `us-gov-east-1` Region.

To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using `CreateStoreImageTask`. In this example, the S3 bucket is located in `us-east-2`. For an example command, see [Store an AMI in an S3 bucket \(p. 191\)](#).
- Monitor the progress of the store task by using `DescribeStoreImageTasks`. The object becomes visible in the S3 bucket when the task is completed. For an example command, see [Describe the progress of an AMI store task \(p. 191\)](#).
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in `us-gov-east-1`.

Note

Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.

- To copy one AMI across partitions, the copy process could be as straightforward as the following: [Download the object](#) from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then [upload the object](#) from the intermediate host to the source bucket. For each stage of the process, use the AWS credentials for the partition.
- For more sustained usage, consider developing an application that manages the copies, potentially using S3 [multipart downloads and uploads](#).
- Restore the AMI from the S3 bucket in the target partition by using `CreateRestoreImageTask`. In this example, the S3 bucket is located in `us-gov-east-1`. For an example command, see [Restore an AMI from an S3 bucket \(p. 192\)](#).

- Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

Make archival copies of AMIs

You can make archival copies of AMIs by storing them in an S3 bucket. For an example command, see [Store an AMI in an S3 bucket \(p. 191\)](#).

The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs that contain data that can easily be compressed will result in smaller objects in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see [Amazon S3 Storage Classes](#) and [Amazon S3 pricing](#)

How the AMI store and restore APIs work

To store and restore an AMI using S3, you use the following APIs:

- `CreateStoreImageTask` – Stores the AMI in an S3 bucket
- `DescribeStoreImageTasks` – Provides the progress of the AMI store task
- `CreateRestoreImageTask` – Restores the AMI from an S3 bucket

How the APIs work

- [CreateStoreImageTask \(p. 188\)](#)
- [DescribeStoreImageTasks \(p. 189\)](#)
- [CreateRestoreImageTask \(p. 189\)](#)

CreateStoreImageTask

The [CreateStoreImageTask \(p. 191\)](#) API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an [S3 multipart upload](#) to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a `.bin` extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The time it takes to complete the task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can track the progress of the task by calling the [DescribeStoreImageTasks \(p. 191\)](#) API.

The sum of the sizes of all the AMIs in progress is limited to 600 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For example, if an AMI with 100 GB of snapshot data and another AMI with 200 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 300 GB, which is less than

the limit. But if a single AMI with 800 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The [DescribeStoreImageTasks \(p. 191\)](#) API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is `InProgress`, `Completed`, or `Failed`. For tasks `InProgress`, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The [CreateRestoreImageTask \(p. 192\)](#) API starts a task that restores an AMI from an S3 object that was previously created by using a [CreateStoreImageTask \(p. 191\)](#) request.

The restore task can be performed in the same or a different Region in which the store task was performed.

The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI ([describe-images](#)) or its EBS snapshots ([describe-snapshots](#)). If the task fails, the AMI and snapshots are moved to a failed state.

The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

Limitations

- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to 1 TB.
- Quota on [store image \(p. 191\)](#) requests: 600 GB of storage work (snapshot data) in progress.
- Quota on [restore image \(p. 192\)](#) requests: 300 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can't create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can't be restored with its original AMI ID. You can mitigate this by using [AMI aliasing](#).
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can't store and restore an AMI using the Amazon EC2 console.

Costs

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see [Amazon S3 pricing](#) and [Amazon EBS pricing](#).

Securing your AMIs

To use the store and restore APIs, the S3 bucket and the AMI must be in the same Region. It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can't be done, use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling [Server Side Encryption](#) for the S3 buckets in which you store the AMIs, although it's not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- Blocking public access to your Amazon S3 storage
 - Setting default server-side encryption behavior for Amazon S3 buckets
 - What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?
 - Enabling Amazon S3 server access logging

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

Permissions for storing and restoring AMIs using S3

If your IAM principals will store or restore AMIs using Amazon S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.

You can also create IAM policies that grant principals access to specific resources only. For more example policies, see [Access management for AWS resources](#) in the *IAM User Guide*.

Note

If the snapshots that make up the AMI are encrypted, or if your account is enabled for encryption by default, your IAM principal must have permission to use the KMS key. For more information, see [Permissions to use AWS KMS keys \(p. 1463\)](#).

Work with the AMI store and restore APIs

Topics

- [Store an AMI in an S3 bucket \(p. 191\)](#)
- [Describe the progress of an AMI store task \(p. 191\)](#)
- [Restore an AMI from an S3 bucket \(p. 192\)](#)

Store an AMI in an S3 bucket

To store an AMI (AWS CLI)

Use the [create-store-image-task](#) command. Specify the ID of the AMI and the name of the S3 bucket in which to store the AMI.

```
aws ec2 create-store-image-task \
--image-id ami-1234567890abcdef0 \
--bucket myamibucket
```

Expected output

```
{
    "ObjectKey": "ami-1234567890abcdef0.bin"
}
```

Describe the progress of an AMI store task

To describe the progress of an AMI store task (AWS CLI)

Use the [describe-store-image-tasks](#) command.

```
aws ec2 describe-store-image-tasks
```

Expected output

```
{
    "AmiId": "ami-1234567890abcdef0",
    "Bucket": "myamibucket",
    "ProgressPercentage": 17,
    "S3ObjectKey": "ami-1234567890abcdef0.bin",
    "StoreTaskState": "InProgress",
    "StoreTaskFailureReason": null,
    "TaskStartTime": "2021-01-01T01:01:01.001Z"
```

}

Restore an AMI from an S3 bucket

To restore an AMI (AWS CLI)

Use the [create-restore-image-task](#) command. Using the values for `S3ObjectKey` and `Bucket` from the `describe-store-image-tasks` output, specify the object key of the AMI and the name of the S3 bucket to which the AMI was copied. Also specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account.

Note

The restored AMI gets a new AMI ID.

```
aws ec2 create-restore-image-task \
--object-key ami-1234567890abcdef0.bin \
--bucket myamibucket \
--name "New AMI Name"
```

Expected output

```
{  
    "ImageId": "ami-0eab20fe36f83e1a8"  
}
```

Deprecate an AMI

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must [deregister \(p. 196\)](#) it.

After an AMI is deprecated:

- For AMI users, the deprecated AMI does not appear in [DescribeImages](#) API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in [DescribeImages](#) API calls.
- For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.
- For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.
- EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

You can also create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see [Automate AMI lifecycles \(p. 1498\)](#).

Topics

- [Costs \(p. 193\)](#)
- [Limitations \(p. 189\)](#)
- [Deprecate an AMI \(p. 193\)](#)
- [Describe deprecated AMIs \(p. 194\)](#)
- [Cancel the deprecation of an AMI \(p. 196\)](#)

Costs

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by [deregistering \(p. 196\)](#) it.

Limitations

- To deprecate an AMI, you must be the owner of the AMI.

Deprecate an AMI

You can deprecate an AMI on a specific date and time. You must be the AMI owner to perform this procedure.

Console

To deprecate an AMI on a specific date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to set the same deprecation date of several AMIs at once.
5. Select the **Enable** check box, and then enter the deprecation date and time.
6. Choose **Save**.

AWS CLI

To deprecate an AMI on a specific date

Use the `enable-image-deprecation` command. Specify the ID of the AMI and the date and time on which to deprecate the AMI. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

```
aws ec2 enable-image-deprecation \
--image-id ami-1234567890abcdef0 \
--deprecate-at "2021-10-15T13:17:12.000Z"
```

Expected output

```
{  
    "Return": "true"
```

}

Describe deprecated AMIs

You can view the deprecation date and time of an AMI, and filter all the AMIs by deprecation date. You can also use the AWS CLI to describe all the AMIs that have been deprecated, where the deprecation date is in the past.

Console

To view the deprecation date of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**, and then select the AMI.
3. Check the **Deprecation time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the deprecation date and time of the AMI. If the field is empty, the AMI is not deprecated.

To filter AMIs by deprecation date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me** or **Private images** (private images include AMIs that are shared with you as well as owned by you).
4. In the Search bar, enter **Deprecation time** (as you enter the letters, the **Deprecation time** filter appears), and then choose an operator and a date and time.

AWS CLI

When you describe all AMIs using the [describe-images](#) command, the results are different depending on whether you are an AMI user or the AMI owner.

- If you are an AMI user:

By default, when you describe all AMIs using the [describe-images](#) command, deprecated AMIs that are not owned by you, but which are shared with you, do not appear in the results. To include deprecated AMIs in the results, you must specify the `--include-deprecated true` parameter. The default value for `--include-deprecated` is `false`. If you omit this parameter, deprecated AMIs do not appear in the results.

- If you are the AMI owner:

When you describe all AMIs using the [describe-images](#) command, all the AMIs that you own, including deprecated AMIs, appear in the results. You do not need to specify the `--include-deprecated true` parameter. Furthermore, you cannot exclude deprecated AMIs that you own from the results by using `--include-deprecated false`.

If an AMI is deprecated, the `DeprecationTime` field appears in the results.

Note

A deprecated AMI is an AMI whose deprecation date is in the past. If you have set the deprecation date to a date in the future, the AMI is not yet deprecated.

To include all deprecated AMIs when describing all AMIs

Use the [describe-images](#) command and specify the `--include-deprecated` parameter with a value of `true` to include all deprecated AMIs that are not owned by you in the results.

```
aws ec2 describe-images \
--region us-east-1 \
--owners 123456example
--include-deprecated true
```

To describe the deprecation date of an AMI

Use the [describe-images](#) command and specify the ID of the AMI.

Note that if you specify `--include-deprecated false` together with the AMI ID, the deprecated AMI will be returned in the results.

```
aws ec2 describe-images \
--region us-east-1 \
--image-ids ami-1234567890EXAMPLE
```

Expected output

The `DeprecationTime` field displays the date on which the AMI is set to be deprecated. If the AMI is not set to be deprecated, the `DeprecationTime` field does not appear in the output.

Cancel the deprecation of an AMI

You can cancel the deprecation of an AMI, which removes the date and time from the **Deprecation time** field (console) or the **DeprecationTime** field from the **describe-images** output (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To cancel the deprecation of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to cancel the deprecation of several AMIs at once.
5. Clear the **Enable** check box, and then choose **Save**.

AWS CLI

To cancel the deprecation of an AMI

Use the **disable-image-deprecation** command and specify the ID of the AMI.

```
aws ec2 disable-image-deprecation \
--image-id ami-1234567890abcdef0
```

Expected output

```
{  
    "Return": "true"  
}
```

Deregister your Linux AMI

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances.

When you deregister an AMI, it doesn't affect any instances that you've already launched from the AMI. You'll continue to incur usage costs for these instances. Therefore, if you are finished with these instances, you should terminate them.

The procedure that you'll use to clean up your AMI depends on whether it is backed by Amazon EBS or instance store. For more information, see [Determine the root device type of your AMI \(p. 107\)](#).

Contents

- [Considerations \(p. 196\)](#)
- [Clean up your Amazon EBS-backed AMI \(p. 197\)](#)
- [Clean up your instance store-backed AMI \(p. 199\)](#)

Considerations

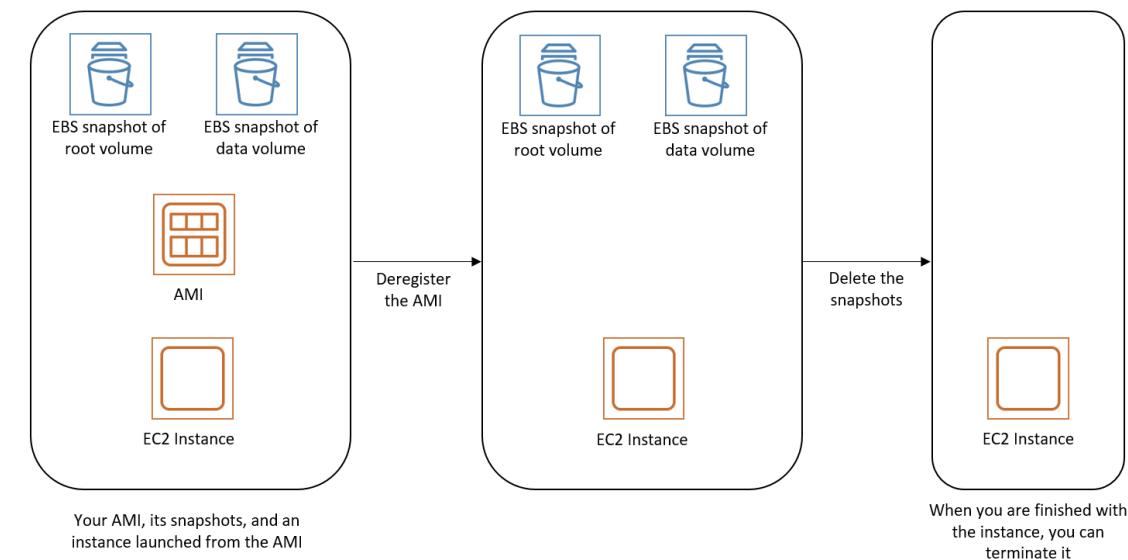

The following considerations apply to deregistering AMIs:

- You can't deregister an AMI that is not owned by your account.
- You can't deregister an AMI that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault.

Clean up your Amazon EBS-backed AMI

When you deregister an Amazon EBS-backed AMI, it doesn't affect the snapshot(s) that were created for the volume(s) of the instance during the AMI creation process. You'll continue to incur storage costs for the snapshots. Therefore, if you are finished with the snapshots, you should delete them.

The following diagram illustrates the process for cleaning up your Amazon EBS-backed AMI.

You can use one of the following methods to clean up your Amazon EBS-backed AMI.

New console

To clean up your Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. **Deregister the AMI**
 - a. In the navigation pane, choose **AMIs**.
 - b. Select the AMI to deregister, and take note of its ID—this can help you find the snapshots to delete in the next step.
 - c. Choose **Actions, Deregister AMI**. When prompted for confirmation, choose **Deregister AMI**.

Note
It might take a few minutes before the console removes the AMI from the list.
Choose **Refresh** to refresh the status.
3. **Delete snapshots that are no longer needed**
 - a. In the navigation pane, choose **Snapshots**.
 - b. Select a snapshot to delete (look for the AMI ID from the prior step in the **Description** column).
 - c. Choose **Actions, Delete snapshot**. When prompted for confirmation, choose **Delete**.
4. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it.

- a. In the navigation pane, choose **Instances** then select the instance to terminate.
- b. Choose **Instance state, Terminate instance**. When prompted for confirmation, choose **Terminate**.

Old console

To clean up your Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. **Deregister the AMI**
 - a. In the navigation pane, choose **AMIs**.
 - b. Select the AMI to deregister, and take note of its ID — this can help you find the snapshots to delete in the next step.
 - c. Choose **Actions, Deregister**. When prompted for confirmation, choose **Continue**.

Note
It may take a few minutes before the console removes the AMI from the list.
Choose **Refresh** to refresh the status.
3. **Delete snapshots that are no longer needed**
 - a. In the navigation pane, choose **Snapshots**.
 - b. Select a snapshot to delete (look for the AMI ID from the prior step in the **Description** column).
 - c. Choose **Actions, Delete**. When prompted for confirmation, choose **Yes, Delete**.
4. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it.

 - a. In the navigation pane, choose **Instances** then select the instance to terminate.
 - b. Choose **Actions, Instance State, Terminate**. When prompted for confirmation, choose **Yes, Terminate**.

AWS CLI

Follow these steps to clean up your Amazon EBS-backed AMI using the AWS CLI

1. Deregister the AMI

Deregister the AMI using the [deregister-image](#) command:

```
aws ec2 deregister-image --image-id ami-12345678
```

2. Delete snapshots that are no longer needed

Delete snapshots that are no longer needed by using the [delete-snapshot](#) command:

```
aws ec2 delete-snapshot --snapshot-id snap-1234567890abcdef0
```

3. Terminate instances (Optional)

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [terminate-instances](#) command:

```
aws ec2 terminate-instances --instance-ids i-12345678
```

PowerShell

Follow these steps to clean up your Amazon EBS-backed AMI using the AWS Tools for Windows PowerShell

1. Deregister the AMI

Deregister the AMI using the [Unregister-EC2Image](#) cmdlet:

```
Unregister-EC2Image -ImageId ami-12345678
```

2. Delete snapshots that are no longer needed

Delete snapshots that are no longer needed by using the [Remove-EC2Snapshot](#) cmdlet:

```
Remove-EC2Snapshot -SnapshotId snap-12345678
```

3. Terminate instances (Optional)

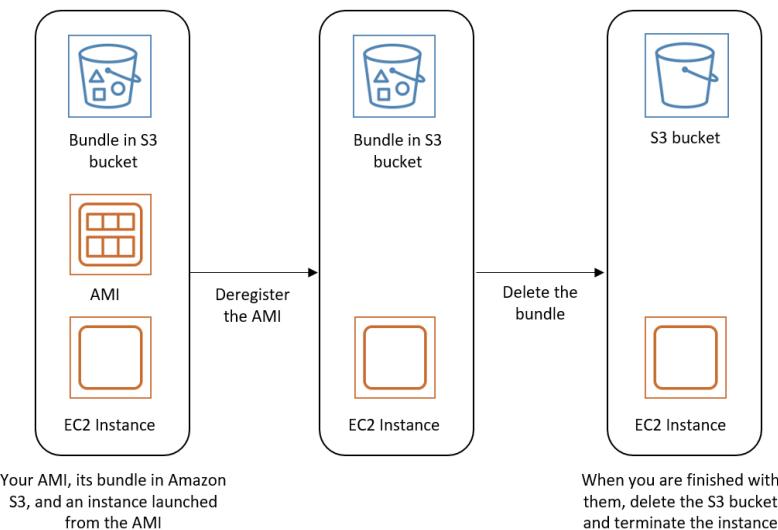

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [Remove-EC2Instance](#) cmdlet:

```
Remove-EC2Instance -InstanceId i-12345678
```

Clean up your instance store-backed AMI

When you deregister an instance store-backed AMI, it doesn't affect the files that you uploaded to Amazon S3 when you created the AMI. You'll continue to incur usage costs for these files in Amazon S3. Therefore, if you are finished with these files, you should delete them.

The following diagram illustrates the process for cleaning up your instance store-backed AMI.

To clean up your instance store-backed AMI

1. Deregister the AMI using the [deregister-image](#) command as follows.

```
aws ec2 deregister-image --image-id ami_id
```

2. Delete the bundle in Amazon S3 using the [ec2-delete-bundle](#) (p. 170) (AMI tools) command as follows.

```
ec2-delete-bundle -b myawsbucket/myami -a your_access_key_id -s your_secret_access_key  
-p image
```

3. (Optional) If you are finished with an instance that you launched from the AMI, you can terminate it using the [terminate-instances](#) command as follows.

```
aws ec2 terminate-instances --instance-ids instance_id
```

4. (Optional) If you are finished with the Amazon S3 bucket that you uploaded the bundle to, you can delete the bucket. To delete an Amazon S3 bucket, open the Amazon S3 console, select the bucket, choose **Actions**, and then choose **Delete**.

Recover AMIs from the Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

AMIs in the Recycle Bin do not incur any additional charges.

For more information, see [Recycle Bin](#) (p. 1664).

Topics

- [Permissions for working with AMIs in the Recycle Bin](#) (p. 200)
- [View AMIs in the Recycle Bin](#) (p. 201)
- [Restore AMIs from the Recycle Bin](#) (p. 202)

Permissions for working with AMIs in the Recycle Bin

By default, IAM users don't have permission to work with AMIs that are in the Recycle Bin. To allow IAM users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. You then attach those policies to the IAM users or the groups that require those permissions.

To view and recover AMIs that are in the Recycle Bin, AWS Identity and Access Management (IAM) users must have the following permissions:

- `ec2:ListImagesInRecycleBin`
- `ec2:RestoreImageFromRecycleBin`

To manage tags for AMIs in the Recycle Bin, IAM users need the following additional permissions.

- `ec2:CreateTags`
- `ec2:DeleteTags`

To use the Recycle Bin console, IAM users need the `ec2:DescribeTags` permission.

The following is an example IAM policy. It includes the `ec2:DescribeTags` permission for console users, and it includes the `ec2:CreateTags` and `ec2:DeleteTags` permissions for managing tags. If the permissions are not needed, you can remove them from the policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2>ListImagesInRecycleBin",  
                "ec2>RestoreImageFromRecycleBin"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2>CreateTags",  
                "ec2>DeleteTags",  
                "ec2>DescribeTags"  
            ],  
            "Resource": "arn:aws:ec2:Region::image/*"  
        }  
    ]  
}
```

For more information about the permissions needed to use Recycle Bin, see [Permissions for working with Recycle Bin and retention rules \(p. 1667\)](#).

View AMIs in the Recycle Bin

While an AMI is in the Recycle Bin, you can view limited information about it, including:

- The name, description, and unique ID of the AMI.
- The date and time when the AMI was deleted and it entered Recycle Bin.
- The date and time when the retention period expires. The AMI will be permanently deleted at this time.

You can view the AMIs in the Recycle Bin using one of the following methods.

Recycle Bin console

To view deleted AMIs in the Recycle Bin using the console

1. Open the Recycle Bin console at console.aws.amazon.com/rbin/home/
2. In the navigation panel, choose **Recycle Bin**.
3. The grid lists all of the resources that are currently in the Recycle Bin. To view the details for a specific AMI, select it in the grid, and choose **Actions, View details**.

AWS CLI

To view deleted AMIs in the Recycle Bin using the AWS CLI

Use the [list-images-in-recycle-bin](#) AWS CLI command. To view specific AMIs, include the `--image-id` option and specify the IDs of the AMIs to view. You can specify up to 20 IDs in a single request.

To view all of the AMIs in the Recycle Bin, omit the `--image-id` option. If you do not specify a value for `--max-items`, the command returns 1,000 items per page, by default. For more information, see [Pagination](#) in the *Amazon EC2 API Reference*.

```
$ aws ec2 list-images-in-recycle-bin --image-id ami_id
```

For example, the following command provides information about AMI `ami-01234567890abcdef` in the Recycle Bin.

```
$ aws ec2 list-images-in-recycle-bin --image-id ami-01234567890abcdef
```

Example output:

```
{
  "Images": [
    {
      "ImageId": "ami-0f740206c743d75df",
      "Name": "My AL2 AMI",
      "Description": "My Amazon Linux 2 AMI",
      "RecycleBinEnterTime": "2021-11-26T21:04:50+00:00",
      "RecycleBinExitTime": "2022-03-06T21:04:50+00:00"
    }
  ]
}
```

Restore AMIs from the Recycle Bin

You can't use an AMI in any way while it is in the Recycle Bin. To use the AMI, you must first restore it. When you restore an AMI from the Recycle Bin, the AMI is immediately available for use, and it is removed from the Recycle Bin. You can use a restored AMI in the same way that you use any other AMI in your account.

You can restore an AMI from the Recycle Bin using one of the following methods.

Recycle Bin console

To restore an AMI from the Recycle Bin using the console

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation panel, choose **Recycle Bin**.
3. The grid lists all of the resources that are currently in the Recycle Bin. Select the AMI to restore, and choose **Recover**.
4. When prompted, choose **Recover**.

AWS CLI

To restore a deleted AMI from the Recycle Bin using the AWS CLI

Use the [restore-image-from-recycle-bin](#) AWS CLI command. For `--image-id`, specify the ID of the AMI to restore.

```
$ aws ec2 restore-image-from-recycle-bin --image-id ami_id
```

For example, the following command restores AMI `ami-01234567890abcdef` from the Recycle Bin.

```
$ aws restore-image-from-recycle-bin --image-id ami-01234567890abcdef
```

The command returns no output on success.

Automate the EBS-backed AMI lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. For more information, see [Amazon Data Lifecycle Manager \(p. 1485\)](#).

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see [Shared AMIs \(p. 122\)](#).

Encryption with EBS-backed AMIs topics

- [Instance-launching scenarios \(p. 203\)](#)
- [Image-copying scenarios \(p. 206\)](#)

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the `RunInstances` action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information about block device mapping, see [Block device mapping](#). For examples of controlling block device mapping from the AWS CLI, see [Launch, List, and Terminate EC2 Instances](#).

By default, without explicit encryption parameters, a `RunInstances` action maintains the existing encryption state of an AMI's source snapshots while restoring EBS volumes from them. If [Encryption by](#)

[default \(p. 1545\)](#) is enabled, all volumes created from the AMI (whether from encrypted or unencrypted snapshots) will be encrypted. If encryption by default is not enabled, then the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

Launch with no encryption parameters

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Instance launch behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

Instance with both `Encrypted` and `KmsKeyId` set

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.

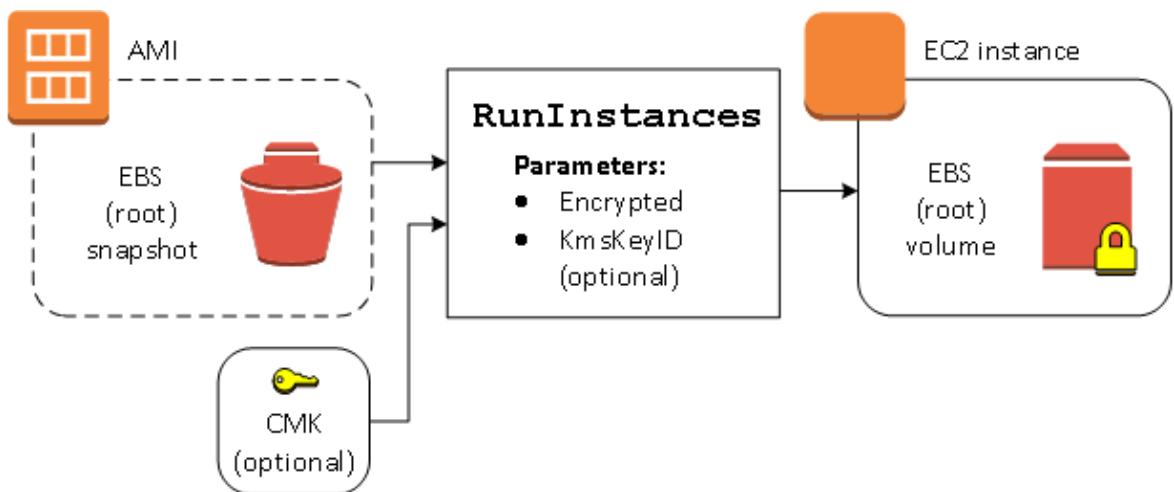

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the `RunInstances` action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see [Launch your instance \(p. 578\)](#).

Encrypt a volume during launch

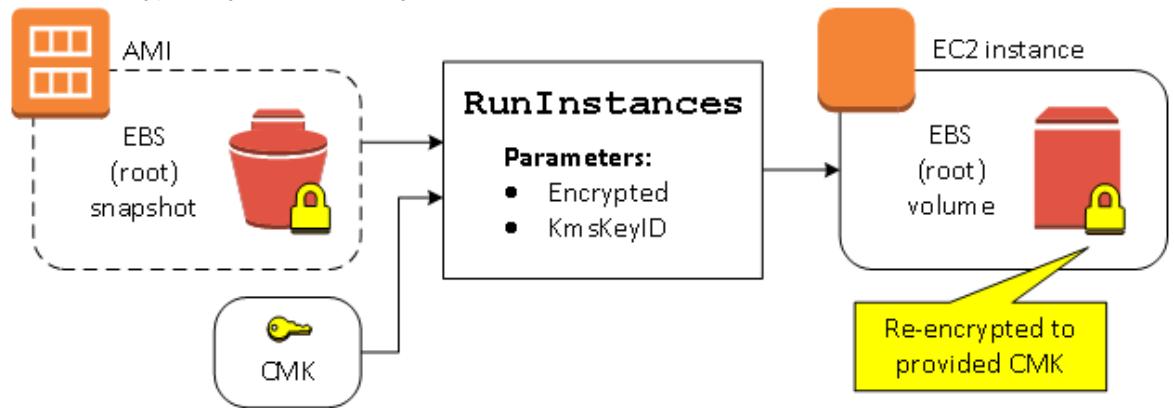

In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.

The `Encrypted` parameter alone results in the volume for this instance being encrypted. Providing a `KmsKeyId` parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the `KmsKeyId` parameter.

Re-encrypt a volume during launch

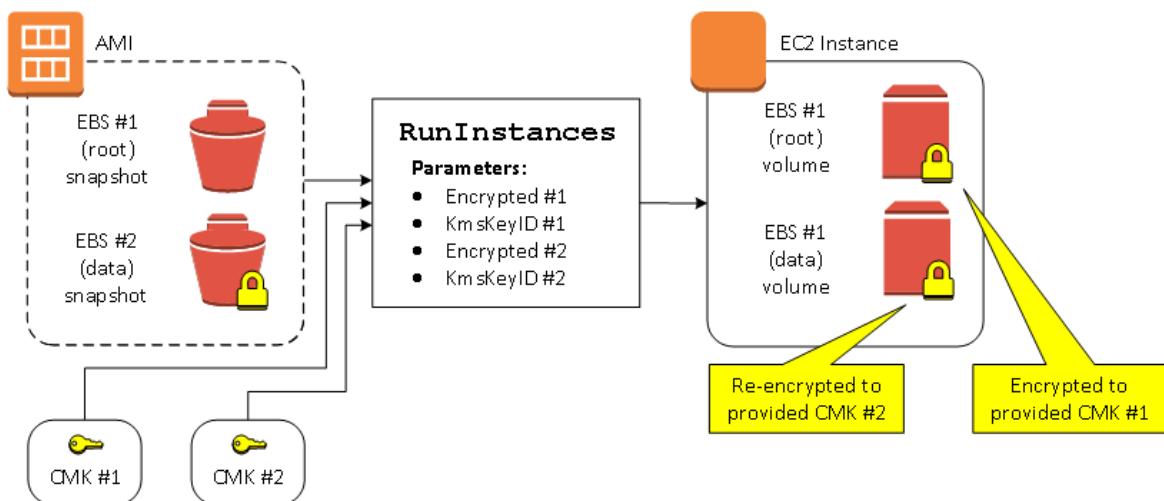

In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.

If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

Change encryption state of multiple volumes during launch

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.

In this scenario, the `RunInstances` action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.

Image-copying scenarios

Amazon EC2 AMIs are copied using the `CopyImage` action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a `CopyImage` action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

Copy with no encryption parameters

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
- An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
- An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Copy-image behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
- An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

Copy-image behaviors with both `Encrypted` and `KmsKeyId` set

- An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.
- An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

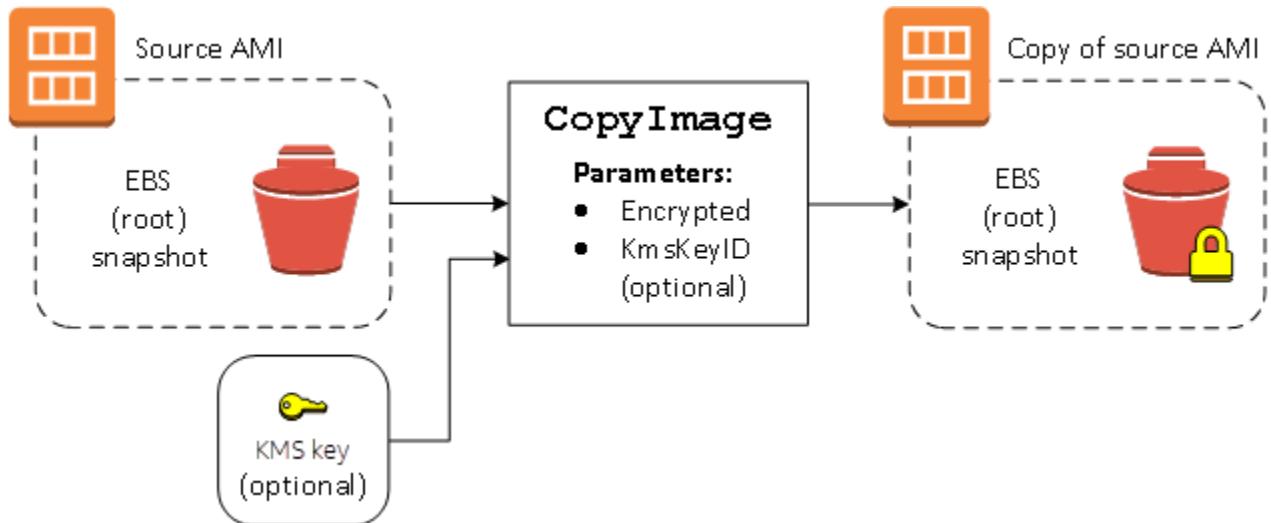

For detailed instructions using the console, see [Copy an AMI \(p. 180\)](#).

Encrypt an unencrypted image during copy

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling [encryption by default \(p. 1545\)](#) has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.

Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

Note

You can also copy an image with multiple snapshots and configure the encryption state of each individually.

Understand AMI billing information

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose

when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the **AMI Platform details** to confirm that the AMI is supported for Spot Instances.
- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the **AMI Platform details**.

For more information about instance pricing, see [Amazon EC2 pricing](#).

AMI billing information fields

The following fields provide billing information associated with an AMI:

Platform details

The platform details associated with the billing code of the AMI. For example, Red Hat Enterprise Linux.

Usage operation

The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, RunInstances:0010. **Usage operation** corresponds to the **lineitem/Operation** column on your AWS Cost and Usage Report (CUR) and in the [AWS Price List API](#).

You can view these fields on the **Instances** or **AMIs** page in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the **Instances** or **AMIs** pages in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) command.

Platform details	Usage operation **
Linux/UNIX	RunInstances
Red Hat BYOL Linux	RunInstances:00g0
Red Hat Enterprise Linux	RunInstances:0010
Red Hat Enterprise Linux with HA	RunInstances:1010
Red Hat Enterprise Linux with SQL Server Standard and HA	RunInstances:1014

Platform details	Usage operation **
Red Hat Enterprise Linux with SQL Server Enterprise and HA	RunInstances:1110
Red Hat Enterprise Linux with SQL Server Standard	RunInstances:0014
Red Hat Enterprise Linux with SQL Server Web	RunInstances:0210
Red Hat Enterprise Linux with SQL Server Enterprise	RunInstances:0110
SQL Server Enterprise	RunInstances:0100
SQL Server Standard	RunInstances:0004
SQL Server Web	RunInstances:0200
SUSE Linux	RunInstances:000g
Windows	RunInstances:0002
Windows BYOL	RunInstances:0800
Windows with SQL Server Enterprise *	RunInstances:0102
Windows with SQL Server Standard *	RunInstances:0006
Windows with SQL Server Web *	RunInstances:0202

* If two software licenses are associated with an AMI, the **Platform details** field shows both.

** If you are running Spot Instances, the [lineitem/Operation](#) on your AWS Cost and Usage Report might be different from the **Usage operation** value that is listed here. For example, if [lineitem/Operation](#) displays RunInstances:0010:SV006, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (Virginia) in VPC Zone #6.

Finding AMI billing and usage details

In the Amazon EC2 console, you can view the AMI billing information from the **AMIs** page or from the **Instances** page. You can also find billing information using the AWS CLI or the instance metadata service.

The following fields can help you verify AMI charges on your bill:

- **Platform details**
- **Usage operation**
- **AMI ID**

Find AMI billing information (console)

Follow these steps to view AMI billing information in the Amazon EC2 console:

Look up AMI billing information from the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select an AMI.

3. On the **Details** tab, check the values for **Platform details** and **Usage operation**.

Look up AMI billing information from the Instances page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select an instance.
3. On the **Details** tab (or the **Description** tab if you are using the prior version of the console), check the values for **Platform details** and **Usage operation**.

Find AMI billing information (AWS CLI)

To find the AMI billing information using the AWS CLI, you need to know the AMI ID. If you don't know the AMI ID, you can get it from the instance using the [describe-instances](#) command.

To find the AMI ID

If you know the instance ID, you can get the AMI ID for the instance by using the [describe-instances](#) command.

```
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

In the output, the AMI ID is specified in the `ImageId` field.

```
... "Instances": [  
{  
    "AmiLaunchIndex": 0,  
    "ImageId": "ami-0123456789EXAMPLE",  
    "InstanceId": "i-123456789abcde123",  
    ...  
}]
```

To find the AMI billing information

If you know the AMI ID, you can use the [describe-images](#) command to get the AMI platform and usage operation details.

```
$ aws ec2 describe-images --image-ids ami-0123456789EXAMPLE
```

The following example output shows the `PlatformDetails` and `UsageOperation` fields. In this example, the `ami-0123456789EXAMPLE` platform is Red Hat Enterprise Linux and the usage operation and billing code is `RunInstances:0010`.

Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the [lineitem/Operation](#) column. That value should match the value for **Usage operation** that's associated with the AMI.

For example, the AMI ami-0123456789EXAMPLE has the following billing information:

- **Platform details** = Red Hat Enterprise Linux
- **Usage operation** = RunInstances:0010

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the [lineitem/Operation](#) column. In this example, the value should be RunInstances:0010.

Amazon Linux

Amazon Linux is provided by Amazon Web Services (AWS). It is designed to provide a stable, secure, and high-performance execution environment for applications running on Amazon EC2. It also includes packages that enable easy integration with AWS, including launch configuration tools and many popular AWS libraries and tools. AWS provides ongoing security and maintenance updates for all instances running Amazon Linux. Many applications developed on CentOS (and similar distributions) run on Amazon Linux.

Amazon Linux availability

AWS provides Amazon Linux 2 and the Amazon Linux AMI. If you are migrating from another Linux distribution to Amazon Linux, we recommend that you migrate to Amazon Linux 2.

The last version of the Amazon Linux AMI, 2018.03, reaches the end of standard support on December 31, 2020. For more information, see the following blog post: [Amazon Linux AMI end of life](#). If you are currently using the Amazon Linux AMI, we recommend that you migrate to Amazon Linux 2. To migrate to Amazon Linux 2, launch an instance or create a virtual machine using the current Amazon Linux 2 image. Install your applications, plus any required packages. Test your application, and make any changes required for it to run on Amazon Linux 2.

For more information, see [Amazon Linux 2](#) and [Amazon Linux AMI](#). For Amazon Linux Docker container images, see [amazonlinux](#) on Docker Hub.

Connect to an Amazon Linux instance

Amazon Linux does not allow remote root SSH by default. Also, password authentication is disabled to prevent brute-force password attacks. To enable SSH logins to an Amazon Linux instance, you must provide your key pair to the instance at launch. You must also set the security group used to launch your instance to allow SSH access. By default, the only account that can log in remotely using SSH is ec2-user; this account also has **sudo** privileges. If you enable remote root login, be aware that it is less secure than relying on key pairs and a secondary user.

Identify Amazon Linux images

Each image contains a unique `/etc/image-id` file that identifies it. This file contains the following information about the image:

- `image_name`, `image_version`, `image_arch` — Values from the build recipe that Amazon used to construct the image.
- `image_stamp` — A unique, random hex value generated during image creation.
- `image_date` — The UTC time of image creation, in `YYYYMMDDhhmmss` format
- `recipe_name`, `recipe_id` — The name and ID of the build recipe Amazon used to construct the image.

Amazon Linux contains an `/etc/system-release` file that specifies the current release that is installed. This file is updated using `yum` and is part of the `system-release` RPM.

Amazon Linux also contains a machine-readable version of `/etc/system-release` that follows the CPE specification; see `/etc/system-release-cpe`.

Amazon Linux 2

The following is an example of `/etc/image-id` for the current version of Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn2-ami-hvm"
image_version="2"
image_arch="x86_64"
image_file="amzn2-ami-hvm-2.0.20180810-x86_64.xfs.gpt"
image_stamp="8008-2abd"
image_date="20180811020321"
recipe_name="amzn2 ami"
recipe_id="c652686a-2415-9819-65fb-4dee-9792-289d-1e2846bd"
```

The following is an example of `/etc/system-release` for the current version of Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/system-release
Amazon Linux 2
```

The following is an example of `/etc/os-release` for Amazon Linux 2:

```
[ec2-user ~]$ cat /etc/os-release
NAME="Amazon Linux"
VERSION="2"
ID="amzn"
ID_LIKE="centos rhel fedora"
VERSION_ID="2"
PRETTY_NAME="Amazon Linux 2"
ANSI_COLOR="0;33"
CPE_NAME="cpe:2.3:o:amazon:amazon_linux:2"
HOME_URL="https://amazonlinux.com/"
```

Amazon Linux AMI

The following is an example of `/etc/image-id` for the current Amazon Linux AMI:

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn-ami-hvm"
image_version="2018.03"
image_arch="x86_64"
image_file="amzn-ami-hvm-2018.03.0.20180811-x86_64.ext4.gpt"
image_stamp="cc81-f2f3"
image_date="20180811012746"
recipe_name="amzn ami"
recipe_id="5b283820-dc60-a7ea-d436-39fa-439f-02ea-5c802dbd"
```

The following is an example of `/etc/system-release` for the current Amazon Linux AMI:

```
[ec2-user ~]$ cat /etc/system-release
Amazon Linux AMI release 2018.03
```

AWS command line tools

The following command line tools for AWS integration and usage are included in the Amazon Linux AMI, or in the default repositories for Amazon Linux 2. For the complete list of packages in the Amazon Linux AMI, see [Amazon Linux AMI 2017.09 Packages](#).

- aws-amitools-ec2
- aws-apitools-as
- aws-apitools-cfn
- aws-apitools-elb

- aws-apitools-mon
- aws-cfn-bootstrap
- aws-cli

Amazon Linux 2 and the minimal versions of Amazon Linux (amzn-ami-minimal-* and amzn2-ami-minimal-*) do not always contain all of these packages; however, you can install them from the default repositories using the following command:

```
[ec2-user ~]$ sudo yum install -y package_name
```

For instances launched using IAM roles, a simple script has been included to prepare `AWS_CREDENTIAL_FILE`, `JAVA_HOME`, `AWS_PATH`, `PATH`, and product-specific environment variables after a credential file has been installed to simplify the configuration of these tools.

Also, to allow the installation of multiple versions of the API and AMI tools, we have placed symbolic links to the desired versions of these tools in `/opt/aws`, as described here:

`/opt/aws/bin`

Symbolic links to `/bin` directories in each of the installed tools directories.

`/opt/aws/{apitools|amitools}`

Products are installed in directories of the form `name-version` and a symbolic link `name` that is attached to the most recently installed version.

`/opt/aws/{apitools|amitools}/name/environment.sh`

Used by `/etc/profile.d/aws-apitools-common.sh` to set product-specific environment variables, such as `EC2_HOME`.

Package repository

Amazon Linux 2 and the Amazon Linux AMI are designed to be used with online package repositories hosted in each Amazon EC2 AWS Region. These repositories provide ongoing updates to packages in Amazon Linux 2 and the Amazon Linux AMI, as well as access to hundreds of additional common open-source server applications. The repositories are available in all Regions and are accessed using `yum` update tools. Hosting repositories in each Region enables us to deploy updates quickly and without any data transfer charges.

Amazon Linux 2 and the Amazon Linux AMI are updated regularly with security and feature enhancements. If you do not need to preserve data or customizations for your instances, you can simply launch new instances using the current AMI. If you need to preserve data or customizations for your instances, you can maintain those instances through the Amazon Linux package repositories. These repositories contain all the updated packages. You can choose to apply these updates to your running instances. Older versions of the AMI and update packages continue to be available for use, even as new versions are released.

Important

Your instance must have access to the internet in order to access the repository.

To install packages, use the following command:

```
[ec2-user ~]$ sudo yum install package
```

For the Amazon Linux AMI, access to the Extra Packages for Enterprise Linux (EPEL) repository is configured, but it is not enabled by default. Amazon Linux 2 is not configured to use the EPEL repository.

EPEL provides third-party packages in addition to those that are in the repositories. The third-party packages are not supported by AWS. You can enable the EPEL repository with the following commands:

- For Amazon Linux 2:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
```

- For the Amazon Linux AMI:

```
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

If you find that Amazon Linux does not contain an application you need, you can simply install the application directly on your Amazon Linux instance. Amazon Linux uses RPMs and **yum** for package management, and that is likely the simplest way to install new applications. You should always check to see if an application is available in our central Amazon Linux repository first, because many applications are available there. These applications can easily be added to your Amazon Linux instance.

To upload your applications onto a running Amazon Linux instance, use **scp** or **sftp** and then configure the application by logging on to your instance. Your applications can also be uploaded during the instance launch by using the **PACKAGE_SETUP** action from the built-in cloud-init package. For more information, see [cloud-init \(p. 217\)](#).

Security updates

Security updates are provided using the package repositories as well as updated AMI security alerts are published in the [Amazon Linux Security Center](#). For more information about AWS security policies or to report a security problem, go to the [AWS Security Center](#).

Amazon Linux is configured to download and install critical or important security updates at launch time. We recommend that you make the necessary updates for your use case after launch. For example, you may want to apply all updates (not just security updates) at launch, or evaluate each update and apply only the ones applicable to your system. This is controlled using the following cloud-init setting: `repo_upgrade`. The following snippet of cloud-init configuration shows how you can change the settings in the user data text you pass to your instance initialization:

```
#cloud-config
repo_upgrade: security
```

The possible values for `repo_upgrade` are as follows:

`critical`

Apply outstanding critical security updates.

`important`

Apply outstanding critical and important security updates.

`medium`

Apply outstanding critical, important, and medium security updates.

`low`

Apply all outstanding security updates, including low-severity security updates.

`security`

Apply outstanding critical or important updates that Amazon marks as security updates.

`bugfix`

Apply updates that Amazon marks as bug fixes. Bug fixes are a larger set of updates, which include security updates and fixes for various other minor bugs.

`all`

Apply all applicable available updates, regardless of their classification.

`none`

Do not apply any updates to the instance on startup.

The default setting for `repo_upgrade` is `security`. That is, if you don't specify a different value in your user data, by default, Amazon Linux performs the security upgrades at launch for any packages installed at that time. Amazon Linux also notifies you of any updates to the installed packages by listing the number of available updates upon login using the `/etc/motd` file. To install these updates, you need to run `sudo yum upgrade` on the instance.

Repository configuration

With Amazon Linux, AMIs are treated as snapshots in time, with a repository and update structure that always gives you the latest packages when you run `yum update -y`.

The repository structure is configured to deliver a continuous flow of updates that enable you to roll from one version of Amazon Linux to the next. For example, if you launch an instance from an older version of the Amazon Linux AMI (such as 2017.09 or earlier) and run `yum update -y`, you end up with the latest packages.

You can disable rolling updates by enabling the *lock-on-launch* feature. The lock-on-launch feature locks your instance to receive updates only from the specified release of the AMI. For example, you can launch a 2017.09 AMI and have it receive only the updates that were released prior to the 2018.03 AMI, until you are ready to migrate to the 2018.03 AMI.

Important

If you lock to a version of the repositories that is not the latest, you do not receive further updates. To receive a continuous flow of updates, you must use the latest AMI, or consistently update your AMI with the repositories pointed to latest.

To enable lock-on-launch in new instances, launch it with the following user data passed to cloud-init:

```
#cloud-config
repo_releasever: 2017.09
```

To lock existing instances to their current AMI version

1. Edit `/etc/yum.conf`.
2. Comment out `releasever=latest`.
3. To clear the cache, run `yum clean all`.

Extras library (Amazon Linux 2)

With Amazon Linux 2, you can use the Extras Library to install application and software updates on your instances. These software updates are known as *topics*. You can install a specific version of a topic or omit the version information to use the most recent version.

To list the available topics, use the following command:

```
[ec2-user ~]$ amazon-linux-extras list
```

To enable a topic and install the latest version of its package to ensure freshness, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic
```

To enable topics and install specific versions of their packages to ensure stability, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic=version topic=version
```

To remove a package installed from a topic, use the following command:

```
[ec2-user ~]$ sudo yum remove $(yum list installed | grep amzn2extra-topic | awk '{ print $1 }')
```

Note

This command does not remove packages that were installed as dependencies of the extra.

To disable a topic and make the packages inaccessible to the yum package manager, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras disable topic
```

Important

This command is intended for advanced users. Improper usage of this command could cause package compatibility conflicts.

Access source packages for reference

You can view the source of packages you have installed on your instance for reference purposes by using tools provided in Amazon Linux. Source packages are available for all of the packages included in Amazon Linux and the online package repository. Simply determine the package name for the source package you want to install and use the **yumdownloader --source** command to view source within your running instance. For example:

```
[ec2-user ~]$ yumdownloader --source bash
```

The source RPM can be unpacked, and, for reference, you can view the source tree using standard RPM tools. After you finish debugging, the package is available for use.

cloud-init

The cloud-init package is an open-source application built by Canonical that is used to bootstrap Linux images in a cloud computing environment, such as Amazon EC2. Amazon Linux contains a customized version of cloud-init. It enables you to specify actions that should happen to your instance at boot time. You can pass desired actions to cloud-init through the user data fields when launching an instance. This means you can use common APIs for many use cases and configure them dynamically at startup. Amazon Linux also uses cloud-init to perform initial configuration of the ec2-user account.

For more information, see the [cloud-init documentation](#).

Amazon Linux uses the cloud-init actions found in /etc/cloud/cloud.cfg.d and /etc/cloud/cloud.cfg. You can create your own cloud-init action files in /etc/cloud/cloud.cfg.d. All files

in this directory are read by cloud-init. They are read in lexical order, and later files overwrite values in earlier files.

The cloud-init package performs these (and other) common configuration tasks for instances at boot:

- Set the default locale.
- Set the hostname.
- Parse and handle user data.
- Generate host private SSH keys.
- Add a user's public SSH keys to `.ssh/authorized_keys` for easy login and administration.
- Prepare the repositories for package management.
- Handle package actions defined in user data.
- Execute user scripts found in user data.
- Mount instance store volumes, if applicable.
 - By default, the `ephemeral0` instance store volume is mounted at `/media/ephemeral0` if it is present and contains a valid file system; otherwise, it is not mounted.
 - By default, any swap volumes associated with the instance are mounted (only for `m1.small` and `c1.medium` instance types).
- You can override the default instance store volume mount with the following cloud-init directive:

```
#cloud-config
mounts:
- [ ephemeral0 ]
```

For more control over mounts, see [Mounts](#) in the cloud-init documentation.

- Instance store volumes that support TRIM are not formatted when an instance launches, so you must partition and format them before you can mount them. For more information, see [Instance store volume TRIM support \(p. 1635\)](#). You can use the `disk_setup` module to partition and format your instance store volumes at boot. For more information, see [Disk Setup](#) in the cloud-init documentation.

Supported user-data formats

The cloud-init package supports user-data handling of a variety of formats:

- Gzip
 - If user-data is gzip compressed, cloud-init decompresses the data and handles it appropriately.
- MIME multipart
 - Using a MIME multipart file, you can specify more than one type of data. For example, you could specify both a user-data script and a cloud-config type. Each part of the multipart file can be handled by cloud-init if it is one of the supported formats.
- Base64 decoding
 - If user-data is base64-encoded, cloud-init determines if it can understand the decoded data as one of the supported types. If it understands the decoded data, it decodes the data and handles it appropriately. If not, it returns the base64 data intact.
- User-Data script
 - Begins with `#!` or `Content-Type: text/x-shellscript`.
 - The script is run by `/etc/init.d/cloud-init-user-scripts` during the first boot cycle. This occurs late in the boot process (after the initial configuration actions are performed).
- Include file

- Begins with `#include` or `Content-Type: text/x-include-url`.
- This content is an include file. The file contains a list of URLs, one per line. Each of the URLs is read, and their content passed through this same set of rules. The content read from the URL can be gzipped, MIME-multi-part, or plaintext.
- Cloud Config Data
 - Begins with `#cloud-config` or `Content-Type: text/cloud-config`.
 - This content is cloud-config data. For a commented example of supported configuration formats, see the examples.
- Upstart job (not supported on Amazon Linux 2)
 - Begins with `#upstart-job` or `Content-Type: text/upstart-job`.
 - This content is stored in a file in `/etc/init`, and upstart consumes the content as per other upstart jobs.
- Cloud Boothook
 - Begins with `#cloud-boothook` or `Content-Type: text/cloud-boothook`.
 - This content is boothook data. It is stored in a file under `/var/lib/cloud` and then runs immediately.
 - This is the earliest "hook" available. There is no mechanism provided for running it only one time. The boothook must take care of this itself. It is provided with the instance ID in the environment variable `INSTANCE_ID`. Use this variable to provide a once-per-instance set of boothook data.

Subscribe to Amazon Linux notifications

To be notified when new AMIs are released, you can subscribe using Amazon SNS.

To subscribe to Amazon Linux notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select the Region in which the SNS notification that you are subscribing to was created.
3. In the navigation pane, choose **Subscriptions**, **Create subscription**.
4. For the **Create subscription** dialog box, do the following:
 - a. [Amazon Linux 2] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN):
`arn:aws:sns:us-east-1:137112412989:amazon-linux-2-ami-updates`.
 - b. [Amazon Linux] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN):
`arn:aws:sns:us-east-1:137112412989:amazon-linux-ami-updates`.
 - c. For **Protocol**, choose **Email**.
 - d. For **Endpoint**, enter an email address that you can use to receive the notifications.
 - e. Choose **Create subscription**.
5. You receive a confirmation email with the subject line "AWS Notification - Subscription Confirmation". Open the email and choose **Confirm subscription** to complete your subscription.

Whenever AMIs are released, we send notifications to the subscribers of the corresponding topic. To stop receiving these notifications, use the following procedure to unsubscribe.

To unsubscribe from Amazon Linux notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use the Region in which the SNS notification was created.

3. In the navigation pane, choose **Subscriptions**, select the subscription, and choose **Actions**, **Delete subscriptions**.
4. When prompted for confirmation, choose **Delete**.

Amazon Linux AMI SNS message format

The schema for the SNS message is as follows.

```
{  
    "description": "Validates output from AMI Release SNS message",  
    "type": "object",  
    "properties": {  
        "v1": {

Run Amazon Linux 2 as a virtual machine on premises

Use the Amazon Linux 2 virtual machine (VM) images for on-premises development and testing. These images are available for use on the following virtualization platforms:

- VMWare
- KVM
- VirtualBox (Oracle VM)
- Microsoft Hyper-V

To use the Amazon Linux 2 virtual machine images with one of the supported virtualization platforms, do the following:

- [Step 1: Prepare the seed.iso boot image \(p. 221\)](#)
- [Step 2: Download the Amazon Linux 2 VM image \(p. 223\)](#)
- [Step 3: Boot and connect to your new VM \(p. 223\)](#)

Step 1: Prepare the seed.iso boot image

The `seed.iso` boot image includes the initial configuration information that is needed to boot your new VM, such as the network configuration, host name, and user data.

Note

The `seed.iso` boot image includes only the configuration information required to boot the VM. It does not include the Amazon Linux 2 operating system files.

To generate the `seed.iso` boot image, you need two configuration files:

- `meta-data`—This file includes the hostname and static network settings for the VM.
- `user-data`—This file configures user accounts, and specifies their passwords, key pairs, and access mechanisms. By default, the Amazon Linux 2 VM image creates a `ec2-user` user account. You use the `user-data` configuration file to set the password for the default user account.

To create the `seed.iso` boot disc

1. Create a new folder named `seedconfig` and navigate into it.
2. Create the `meta-data` configuration file.
 - a. Create a new file named `meta-data`.
 - b. Open the `meta-data` file using your preferred editor and add the following.

```
local-hostname: vm_hostname
# eth0 is the default network interface enabled in the image. You can configure
static network settings with an entry like the following.
network-interfaces: |
    auto eth0
    iface eth0 inet static
        address 192.168.1.10
        network 192.168.1.0
        netmask 255.255.255.0
        broadcast 192.168.1.255
```

gateway 192.168.1.254

Replace `vm_hostname` with a VM host name of your choice, and configure the network settings as required.

- c. Save and close the meta-data configuration file.

For an example meta-data configuration file that specifies a VM hostname (`amazonlinux.onprem`), configures the default network interface (`eth0`), and specifies static IP addresses for the necessary network devices, see the [sample Seed.iso file](#).

3. Create the user-data configuration file.

- a. Create a new file named `user-data`.
- b. Open the `user-data` file using your preferred editor and add the following.

```
#cloud-config
#vim:syntax=yaml
users:
# A user by the name `ec2-user` is created in the image by default.
- default
chpasswd:
  list: |
    ec2-user:plain_text_password
# In the above line, do not add any spaces after 'ec2-user:'.
```

Replace `plain_text_password` with a password of your choice for the default `ec2-user` user account.

- c. (Optional) By default, cloud-init applies network settings each time the VM boots. Add the following to prevent cloud-init from applying network settings at each boot, and to retain the network settings applied during the first boot.

```
# NOTE: Cloud-init applies network settings on every boot by default. To retain
network settings from first
boot, add following 'write_files' section:
write_files:
- path: /etc/cloud/cloud.cfg.d/80_disable_network_after_firstboot.cfg
  content: |
    # Disable network configuration after first boot
  network:
    config: disabled
```

- d. Save and close the `user-data` configuration file.

You can also create additional user accounts and specify their access mechanisms, passwords, and key pairs. For more information about the supported directives, see [Modules](#). For an example `user-data` file that creates three additional users and specifies a custom password for the default `ec2-user` user account, see the [sample Seed.iso file](#).

4. Create the `seed.iso` boot image using the `meta-data` and `user-data` configuration files.

For Linux, use a tool such as `genisoimage`. Navigate into the `seedconfig` folder, and run the following command.

```
$ genisoimage -output seed.iso -volid cidata -joliet -rock user-data meta-data
```

For macOS, use a tool such as `hdiutil`. Navigate one level up from the `seedconfig` folder, and run the following command.

```
$ hdiutil makehybrid -o seed.iso -hfs -joliet -iso -default-volume-name cidata  
seedconfig/
```

Step 2: Download the Amazon Linux 2 VM image

We offer a different Amazon Linux 2 VM image for each of the supported virtualization platforms. Download the correct VM image for your chosen platform:

- [VMWare](#)
- [KVM](#)
- [Oracle VirtualBox](#)
- [Microsoft Hyper-V](#)

Step 3: Boot and connect to your new VM

To boot and connect to your new VM, you must have the `seed.iso` boot image (created in Step 1) and an Amazon Linux 2 VM image (downloaded in Step 2). The steps vary depending on your chosen VM platform.

VMWare vSphere

The VM image for VMware is made available in the OVF format.

To boot the VM using VMWare vSphere

1. Create a new datastore for the `seed.iso` file, or add it to an existing datastore.
2. Deploy the OVF template, but do not start the VM yet.
3. In the **Navigator** panel, right-click the new virtual machine and choose **Edit Settings**.
4. On the **Virtual Hardware** tab, for **New device**, choose **CD/DVD Drive**, and then choose **Add**.
5. For **New CD/DVD Drive**, choose **Datastore ISO File**. Select the datastore to which you added the `seed.iso` file, browse to and select the `seed.iso` file, and then choose **OK**.
6. For **New CD/DVD Drive**, select **Connect**, and then choose **OK**.

After you have associated the datastore with the VM, you should be able to boot it.

KVM

To boot the VM using KVM

1. Open the **Create new VM** wizard.
2. For Step 1, choose **Import existing disk image**.
3. For Step 2, browse to and select the VM image. For **OS type** and **Version**, choose **Linux** and **Red Hat Enterprise Linux 7.0** respectively.
4. For Step 3, specify the amount of RAM and the number of CPUs to use.
5. For Step 4, enter a name for the new VM and select **Customize configuration before install**, and choose **Finish**.
6. In the Configuration window for the VM, choose **Add Hardware**.
7. In the **Add New Virtual Hardware** window, choose **Storage**.
8. In the Storage configuration, choose **Select or create custom storage**. For **Device type**, choose **CDROM device**. Choose **Manage**, **Browse Local**, and then navigate to and select the `seed.iso` file. Choose **Finish**.

9. Choose **Begin Installation**.

Oracle VirtualBox

To boot the VM using Oracle VirtualBox

1. Open Oracle VirtualBox and choose **New**.
2. For **Name**, enter a descriptive name for the virtual machine, and for **Type** and **Version**, select **Linux** and **Red Hat (64-bit)** respectively. Choose **Continue**.
3. For **Memory size**, specify the amount of memory to allocate to the virtual machine, and then choose **Continue**.
4. For **Hard disk**, choose **Use an existing virtual hard disk file**, browse to and open the VM image, and then choose **Create**.
5. Before you start the VM, you must load the `seed.iso` file in the virtual machine's virtual optical drive:
 - a. Select the new VM, choose **Settings**, and then choose **Storage**.
 - b. In the **Storage Devices** list, under **Controller: IDE**, choose the *Empty* optical drive.
 - c. In the **Attributes** section for the optical drive, choose the browse button, select **Choose Virtual Optical Disk File**, and then select the `seed.iso` file. Choose **OK** to apply the changes and close the **Settings**.

After you have added the `seed.iso` file to the virtual optical drive, you should be able to start the VM.

Microsoft Hyper-V

The VM image for Microsoft Hyper-V is compressed into a zip file. You must extract the contents of the zip file.

To boot the VM using Microsoft Hyper-V

1. Open the **New Virtual Machine Wizard**.
2. When prompted to select a generation, select **Generation 1**.
3. When prompted to configure the network adapter, for **Connection** choose **External**.
4. When prompted to connect a virtual hard disk, choose **Use an existing virtual hard disk**, choose **Browse**, and then navigate to and select the VM image. Choose **Finish** to create the VM.
5. Right-click the new VM and choose **Settings**. In the **Settings** window, under **IDE Controller 1**, choose **DVD Drive**.
6. For the DVD drive, choose **Image file** and then browse to and select the `seed.iso` file.
7. Apply the changes and start the VM.

After the VM has booted, log in using one of the user accounts that is defined in the `user-data` configuration file. After you have logged in for the first time, you can then disconnect the `seed.iso` boot image from the VM.

Kernel Live Patching on Amazon Linux 2

Kernel Live Patching for Amazon Linux 2 enables you to apply security vulnerability and critical bug patches to a running Linux kernel, without reboots or disruptions to running applications. This allows you to benefit from improved service and application availability, while keeping your infrastructure secure and up to date.

AWS releases two types of kernel live patches for Amazon Linux 2:

- **Security updates**—Include updates for Linux common vulnerabilities and exposures (CVE). These updates are typically rated as *important* or *critical* using the Amazon Linux Security Advisory ratings. They generally map to a Common Vulnerability Scoring System (CVSS) score of 7 and higher. In some cases, AWS might provide updates before a CVE is assigned. In these cases, the patches might appear as bug fixes.
- **Bug fixes**—Include fixes for critical bugs and stability issues that are not associated with CVEs.

AWS provides kernel live patches for an Amazon Linux 2 kernel version for up to 3 months after its release. After the 3-month period, you must update to a later kernel version to continue to receive kernel live patches.

Amazon Linux 2 kernel live patches are made available as signed RPM packages in the existing Amazon Linux 2 repositories. The patches can be installed on individual instances using existing **yum** workflows, or they can be installed on a group of managed instances using AWS Systems Manager.

Kernel Live Patching on Amazon Linux 2 is provided at no additional cost.

- [Work with Kernel Live Patching \(p. 225\)](#)
- [Limitations \(p. 229\)](#)
- [Frequently asked questions \(p. 229\)](#)

Supported configurations and prerequisites

Kernel Live Patching is supported on Amazon EC2 instances and [on-premises virtual machines \(p. 221\)](#) running Amazon Linux 2.

To use Kernel Live Patching on Amazon Linux 2, you must use:

- A 64-bit (x86_64) architecture that is supported by Amazon Linux 2
- Amazon Linux 2 with kernel version 4.14.165–131.185 or later

Note

The 64-bit ARM (arm64) architecture is not supported.

Work with Kernel Live Patching

You can enable and use Kernel Live Patching on individual instances using the command line on the instance itself, or you can enable and use Kernel Live Patching on a group of managed instances using AWS Systems Manager.

The following sections explain how to enable and use Kernel Live Patching on individual instances using the command line.

For more information about enabling and using Kernel Live Patching on a group of managed instances, see [Use Kernel Live Patching on Amazon Linux 2 instances](#) in the *AWS Systems Manager User Guide*.

Enable Kernel Live Patching

Kernel Live Patching is disabled by default on Amazon Linux 2. To use live patching, you must install the **yum** plugin for Kernel Live Patching and enable the live patching functionality.

Prerequisites

Kernel Live Patching requires **binutils**. If you do not have **binutils** installed, install it using the following command:

```
$ sudo yum install binutils
```

To enable Kernel Live Patching

1. Kernel live patches are available for Amazon Linux 2 with kernel version 4.14.165-131.185 or later. To check your kernel version, run the following command.

```
$ sudo yum list kernel
```

2. If you already have a supported kernel version, skip this step. If you do not have a supported kernel version, run the following commands to update the kernel to the latest version and to reboot the instance.

```
$ sudo yum install -y kernel
```

```
$ sudo reboot
```

3. Install the **yum** plugin for Kernel Live Patching.

```
$ sudo yum install -y yum-plugin-kernel-livepatch
```

4. Enable the **yum** plugin for Kernel Live Patching.

```
$ sudo yum kernel-livepatch enable -y
```

This command also installs the latest version of the kernel live patch RPM from the configured repositories.

5. To confirm that the **yum** plugin for kernel live patching has installed successfully, run the following command.

```
$ rpm -qa | grep kernel-livepatch
```

When you enable Kernel Live Patching, an empty kernel live patch RPM is automatically applied. If Kernel Live Patching was successfully enabled, this command returns a list that includes the initial empty kernel live patch RPM.

6. Install the **kpatch** package.

```
$ sudo yum install -y kpatch-runtime
```

7. Update the **kpatch** service if it was previously installed.

```
$ sudo yum update kpatch-runtime
```

8. Start the **kpatch** service. This service loads all of the kernel live patches upon initialization or at boot.

```
$ sudo systemctl enable kpatch.service
```

9. Configure the Amazon Linux 2 Kernel Live Patching repository, which contains the kernel live patches.

```
$ sudo amazon-linux-extras enable livepatch
```

View the available kernel live patches

Amazon Linux security alerts are published to the Amazon Linux Security Center. For more information about the Amazon Linux 2 security alerts, which include alerts for kernel live patches, see the [Amazon Linux Security Center](#). Kernel live patches are prefixed with ALASLIVEPATCH. The Amazon Linux Security Center might not list kernel live patches that address bugs.

You can also discover the available kernel live patches for advisories and CVEs using the command line.

To list all available kernel live patches for advisories

Use the following command.

```
$ yum updateinfo list
```

The following shows example output.

```
Loaded plugins: extras_suggestions, kernel-livepatch, langpacks, priorities, update-motd

To list all available kernel live patches for CVEs

Use the following command.

```
$ yum updateinfo list cves
```

The following shows example output.

```

Apply kernel live patches

You apply kernel live patches using the **yum** package manager in the same way that you would apply regular updates. The **yum** plugin for Kernel Live Patching manages the kernel live patches that are to be applied and eliminates the need to reboot.

Tip

We recommend that you update your kernel regularly using Kernel Live Patching to ensure that it remains secure and up to date.

You can choose to apply a specific kernel live patch, or to apply any available kernel live patches along with your regular security updates.

To apply a specific kernel live patch

1. Get the kernel live patch version using one of the commands described in [View the available kernel live patches \(p. 227\)](#).
2. Apply the kernel live patch for your Amazon Linux 2 kernel.

```
$ sudo yum install kernel-livepatch-kernel_version.x86_64
```

For example, the following command applies a kernel live patch for Amazon Linux 2 kernel version 4.14.165-133.209.

```
$ sudo yum install kernel-livepatch-4.14.165-133.209-1.0-4.amzn2.x86_64
```

To apply any available kernel live patches along with your regular security updates

Use the following command.

```
$ sudo yum update --security
```

Omit the --security option to include bug fixes.

Important

- The kernel version is not updated after applying kernel live patches. The version is only updated to the new version after the instance is rebooted.
- An Amazon Linux 2 kernel receives kernel live patches for a period of three months. After the three month period has lapsed, no new kernel live patches are released for that kernel version. To continue to receive kernel live patches after the three-month period, you must reboot the instance to move to the new kernel version, which will then continue receiving kernel live patches for the next three months. To check the support window for your kernel version, run `yum kernel-livepatch supported`.

View the applied kernel live patches

To view the applied kernel live patches

Use the following command.

```
$ kpatch list
```

The command returns a list of the loaded and installed security update kernel live patches. The following is example output.

```
Loaded patch modules:  
livepatch_cifs_lease_buffer_len [enabled]  
livepatch_CVE_2019_20096 [enabled]  
livepatch_CVE_2020_8648 [enabled]  
  
Installed patch modules:  
livepatch_cifs_lease_buffer_len (4.14.165-133.209.amzn2.x86_64)  
livepatch_CVE_2019_20096 (4.14.165-133.209.amzn2.x86_64)  
livepatch_CVE_2020_8648 (4.14.165-133.209.amzn2.x86_64)
```

Note

A single kernel live patch can include and install multiple live patches.

Disable Kernel Live Patching

If you no longer need to use Kernel Live Patching, you can disable it at any time.

To disable Kernel Live Patching

1. Remove the RPM packages for the applied kernel live patches.

```
$ sudo yum kernel-livepatch disable
```

2. Uninstall the **yum** plugin for Kernel Live Patching.

```
$ sudo yum remove yum-plugin-kernel-livepatch
```

3. Reboot the instance.

```
$ sudo reboot
```

Limitations

Kernel Live Patching has the following limitations:

- While applying a kernel live patch, you can't perform hibernation, use advanced debugging tools (such as SystemTap, kprobes, and eBPF-based tools), or access ftrace output files used by the Kernel Live Patching infrastructure.
- Amazon Linux 2 instances with 64-bit ARM (arm64) architecture are not supported.

Frequently asked questions

For frequently asked questions about Kernel Live Patching for Amazon Linux 2, see the [Amazon Linux 2 Kernel Live Patching FAQ](#).

User provided kernels

If you need a custom kernel on your Amazon EC2 instances, you can start with an AMI that is close to what you want, compile the custom kernel on your instance, and update the bootloader to point to the new kernel. This process varies depending on the virtualization type that your AMI uses. For more information, see [Linux AMI virtualization types \(p. 108\)](#).

Contents

- [HVM AMIs \(GRUB\) \(p. 229\)](#)
- [Paravirtual AMIs \(PV-GRUB\) \(p. 230\)](#)

HVM AMIs (GRUB)

HVM instance volumes are treated like actual physical disks. The boot process is similar to that of a bare metal operating system with a partitioned disk and bootloader, which enables it to work with all currently supported Linux distributions. The most common bootloader is GRUB or GRUB2.

By default, GRUB does not send its output to the instance console because it creates an extra boot delay. For more information, see [Instance console output \(p. 1748\)](#). If you are installing a custom kernel, you should consider enabling GRUB output.

You don't need to specify a fallback kernel, but we recommend that you have a fallback when you test a new kernel. GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel enables the instance to boot even if the new kernel isn't found.

The legacy GRUB for Amazon Linux uses `/boot/grub/menu.1st`. GRUB2 for Amazon Linux 2 uses `/etc/default/grub`. For more information about updating the default kernel in the bootloader, see the documentation for your Linux distribution.

Paravirtual AMIs (PV-GRUB)

Amazon Machine Images that use paravirtual (PV) virtualization use a system called *PV-GRUB* during the boot process. PV-GRUB is a paravirtual bootloader that runs a patched version of GNU GRUB 0.97. When you start an instance, PV-GRUB starts the boot process and then chain loads the kernel specified by your image's `menu.1st` file.

PV-GRUB understands standard `grub.conf` or `menu.1st` commands, which allows it to work with all currently supported Linux distributions. Older distributions such as Ubuntu 10.04 LTS, Oracle Enterprise Linux, or CentOS 5.x require a special "ec2" or "xen" kernel package, while newer distributions include the required drivers in the default kernel package.

Most modern paravirtual AMIs use a PV-GRUB AKI by default (including all of the paravirtual Linux AMIs available in the Amazon EC2 Launch Wizard Quick Start menu), so there are no additional steps that you need to take to use a different kernel on your instance, provided that the kernel you want to use is compatible with your distribution. The best way to run a custom kernel on your instance is to start with an AMI that is close to what you want and then to compile the custom kernel on your instance and modify the `menu.1st` file to boot with that kernel.

You can verify that the kernel image for an AMI is a PV-GRUB AKI. Run the following [describe-images](#) command (substituting your kernel image ID) and check whether the `Name` field starts with `pv-grub`:

```
aws ec2 describe-images --filters Name=image-id,Values=aki-880531cd
```

- [Amazon PV-GRUB Kernel Image IDs \(p. 231\)](#)
- [Update PV-GRUB \(p. 233\)](#)

Limitations of PV-GRUB

PV-GRUB has the following limitations:

- You can't use the 64-bit version of PV-GRUB to start a 32-bit kernel or vice versa.
- You can't specify an Amazon ramdisk image (ARI) when using a PV-GRUB AKI.
- AWS has tested and verified that PV-GRUB works with these file system formats: EXT2, EXT3, EXT4, JFS, XFS, and ReiserFS. Other file system formats might not work.
- PV-GRUB can boot kernels compressed using the gzip, bzip2, lzo, and xz compression formats.
- Cluster AMIs don't support or need PV-GRUB, because they use full hardware virtualization (HVM). While paravirtual instances use PV-GRUB to boot, HVM instance volumes are treated like actual disks, and the boot process is similar to the boot process of a bare metal operating system with a partitioned disk and bootloader.

- PV-GRUB versions 1.03 and earlier don't support GPT partitioning; they support MBR partitioning only.
- If you plan to use a logical volume manager (LVM) with Amazon Elastic Block Store (Amazon EBS) volumes, you need a separate boot partition outside of the LVM. Then you can create logical volumes with the LVM.

Configure GRUB for paravirtual AMIs

To boot PV-GRUB, a `GRUB menu.1st` file must exist in the image; the most common location for this file is `/boot/grub/menu.1st`.

The following is an example of a `menu.1st` configuration file for booting an AMI with a PV-GRUB AKI. In this example, there are two kernel entries to choose from: Amazon Linux 2018.03 (the original kernel for this AMI), and Vanilla Linux 4.16.4 (a newer version of the Vanilla Linux kernel from <https://www.kernel.org/>). The Vanilla entry was copied from the original entry for this AMI, and the `kernel` and `initrd` paths were updated to the new locations. The `default 0` parameter points the bootloader to the first entry it sees (in this case, the Vanilla entry), and the `fallback 1` parameter points the bootloader to the next entry if there is a problem booting the first.

```
default 0
fallback 1
timeout 0
hiddenmenu

title Vanilla Linux 4.16.4
root (hd0)
kernel /boot/vmlinuz-4.16.4 root=LABEL=/ console=hvc0
initrd /boot/initrd.img-4.16.4

title Amazon Linux 2018.03 (4.14.26-46.32.amzn1.x86_64)
root (hd0)
kernel /boot/vmlinuz-4.14.26-46.32.amzn1.x86_64 root=LABEL=/ console=hvc0
initrd /boot/initramfs-4.14.26-46.32.amzn1.x86_64.img
```

You don't need to specify a fallback kernel in your `menu.1st` file, but we recommend that you have a fallback when you test a new kernel. PV-GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel allows the instance to boot even if the new kernel isn't found.

PV-GRUB checks the following locations for `menu.1st`, using the first one it finds:

- `(hd0)/boot/grub`
- `(hd0,0)/boot/grub`
- `(hd0,0)/grub`
- `(hd0,1)/boot/grub`
- `(hd0,1)/grub`
- `(hd0,2)/boot/grub`
- `(hd0,2)/grub`
- `(hd0,3)/boot/grub`
- `(hd0,3)/grub`

Note that PV-GRUB 1.03 and earlier only check one of the first two locations in this list.

Amazon PV-GRUB Kernel Image IDs

PV-GRUB AKIs are available in all Amazon EC2 regions, excluding Asia Pacific (Osaka). There are AKIs for both 32-bit and 64-bit architecture types. Most modern AMIs use a PV-GRUB AKI by default.

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Use the following [describe-images](#) command to get a list of the PV-GRUB AKIs for the current region:

```
aws ec2 describe-images --owners amazon --filters Name=name,Values=pv-grub-* .gz
```

PV-GRUB is the only AKI available in the ap-southeast-2 Region. You should verify that any AMI you want to copy to this Region is using a version of PV-GRUB that is available in this Region.

The following are the current AKI IDs for each Region. Register new AMIs using an hd0 AKI.

Note

We continue to provide hd00 AKIs for backward compatibility in Regions where they were previously available.

Update PV-GRUB

We recommend that you always use the latest version of the PV-GRUB AMI, as not all versions of the PV-GRUB AMI are compatible with all instance types. Also, older versions of PV-GRUB are not available in all regions, so if you copy an AMI that uses an older version to a Region that does not support that version, you will be unable to boot instances launched from that AMI until you update the kernel image. Use the following procedures to check your instance's version of PV-GRUB and update it if necessary.

To check your PV-GRUB version

- Find the kernel ID for your instance.

```
aws ec2 describe-instance-attribute --instance-id instance_id --attribute kernel --region region
```

```
{  
    "InstanceId": "instance_id",  
    "KernelId": "aki-70cb0e10"  
}
```

The kernel ID for this instance is aki-70cb0e10.

2. View the version information of that kernel ID.

```
aws ec2 describe-images --image-ids aki-70cb0e10 --region region  
  
{  
    "Images": [  
        {  
            "VirtualizationType": "paravirtual",  
            "Name": "pv-grub-hd0_1.05-x86_64.gz",  
            ...  
            "Description": "PV-GRUB release 1.05, 64-bit"  
        }  
    ]  
}
```

This kernel image is PV-GRUB 1.05. If your PV-GRUB version is not the newest version (as shown in [Amazon PV-GRUB Kernel Image IDs \(p. 231\)](#)), you should update it using the following procedure.

To update your PV-GRUB version

If your instance is using an older version of PV-GRUB, you should update it to the latest version.

1. Identify the latest PV-GRUB AKI for your Region and processor architecture from [Amazon PV-GRUB Kernel Image IDs \(p. 231\)](#).
2. Stop your instance. Your instance must be stopped to modify the kernel image used.

```
aws ec2 stop-instances --instance-ids instance_id --region region
```

3. Modify the kernel image used for your instance.

```
aws ec2 modify-instance-attribute --instance-id instance_id --kernel kernel_id --region region
```

4. Restart your instance.

```
aws ec2 start-instances --instance-ids instance_id --region region
```

Configure the Amazon Linux 2 MATE desktop connection

The [MATE desktop environment](#) is pre-installed and pre-configured in the AMI with the following description: Amazon Linux 2 with .Net Core, Mono, and MATE Desktop Environment. The environment provides an intuitive graphical user interface for administering Amazon Linux 2 instances with minimal use of the command line. The interface uses graphical representations, such as icons, windows, toolbars, folders, wallpapers, and desktop widgets. Built-in, GUI-based tools are available to perform common tasks. For example, there are tools for adding and removing software, applying updates, organizing files, launching programs, and monitoring system health.

Important

`xrdp` is the remote desktop software bundled in the AMI. By default, `xrdp` uses a self-signed TLS certificate to encrypt remote desktop sessions. Neither AWS nor the `xrdp` maintainers recommend using self-signed certificates in production. Instead, obtain a certificate from an appropriate certificate authority (CA) and install it on your instances. For more information about TLS configuration, see [TLS security layer](#) on the `xrdp` wiki.

Prerequisite

To run the commands shown in this topic, you must install the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, and configure your AWS profile.

Options

1. Install the AWS CLI – For more information, see [Installing the AWS CLI](#) and [Configuration basics](#) in the *AWS Command Line Interface User Guide*.
2. Install the Tools for Windows PowerShell – For more information, see [Installing the AWS Tools for Windows PowerShell](#) and [Shared credentials](#) in the *AWS Tools for Windows PowerShell User Guide*.

Configure the RDP connection

Follow these steps to set up a Remote Desktop Protocol (RDP) connection from your local machine to an Amazon Linux 2 instance running the MATE desktop environment.

1. To get the ID of the AMI for Amazon Linux 2 that includes MATE in the AMI name, use the [describe-images](#) command from your local command line tool.

```
aws ec2 describe-images --filters "Name=name,Values=amzn2*MATE*" --query "Images[*].  
[ImageId,Name,Description]"  
[  
  [  
    "ami-0123example0abc12",  
    "amzn2-x86_64-MATEDE_DOTNET-2020.12.04",  
    ".NET Core 5.0, Mono 6.12, PowerShell 7.1, and MATE DE pre-installed to run  
    your .NET applications on Amazon Linux 2 with Long Term Support (LTS)." ]  
  [  
    "ami-0456example0def34",  
    "amzn2-x86_64-MATEDE_DOTNET-2020.04.14",  
    "Amazon Linux 2 with .Net Core, PowerShell, Mono, and MATE Desktop Environment"  
  ]  
]
```

Choose the AMI that is appropriate for your use.

2. Launch an EC2 instance with the AMI that you located in the previous step. Configure the security group to allow for inbound TCP traffic to port 3389. For more information about configuring security groups, see [Security groups for your VPC](#). This configuration enables you to use an RDP client to connect to the instance.
3. Connect to the instance using [SSH](#). Run the following command on your Linux instance to set the password for `ec2-user`.

```
[ec2-user ~]$ sudo passwd ec2-user
```

4. Install the certificate and key.

If you already have a certificate and key, copy them to the `/etc/xrdp/` directory as follows:

- Certificate — /etc/xrdp/cert.pem
- Key — /etc/xrdp/key.pem

If you do not have a certificate and key, use the following command to generate them in the /etc/xrdp directory.

```
$ sudo openssl req -x509 -sha384 -newkey rsa:3072 -nodes -keyout /etc/xrdp/key.pem -out /etc/xrdp/cert.pem -days 365
```

Note

This command generates a certificate that is valid for 365 days.

5. Open an RDP client on the computer from which you will connect to the instance (for example, Remote Desktop Connection on a computer running Microsoft Windows). Enter ec2-user as the user name and enter the password that you set in the previous step.

To disable the MATE Desktop Environment on your Amazon EC2 instance

You can turn off the GUI environment at any time by running one of the following commands on your Linux instance.

```
[ec2-user ~]$ sudo systemctl disable xrdp
```

```
[ec2-user ~]$ sudo systemctl stop xrdp
```

To enable the MATE Desktop Environment on your Amazon EC2 instance

To turn the GUI back on, you can run one of the following commands on your Linux instance.

```
[ec2-user ~]$ sudo systemctl enable xrdp
```

```
[ec2-user ~]$ sudo systemctl start xrdp
```

Amazon EC2 instances

If you're new to Amazon EC2, see the following topics to get started:

- [What is Amazon EC2? \(p. 1\)](#)
- [Set up to use Amazon EC2 \(p. 5\)](#)
- [Tutorial: Get started with Amazon EC2 Linux instances \(p. 9\)](#)
- [Instance lifecycle \(p. 574\)](#)

Before you launch a production environment, you need to answer the following questions.

Q. What instance type best meets my needs?

Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see [Instance types \(p. 240\)](#).

Q. What purchasing option best meets my needs?

Amazon EC2 supports On-Demand Instances (the default), Spot Instances, and Reserved Instances. For more information, see [Instance purchasing options \(p. 390\)](#).

Q. Which type of root volume meets my needs?

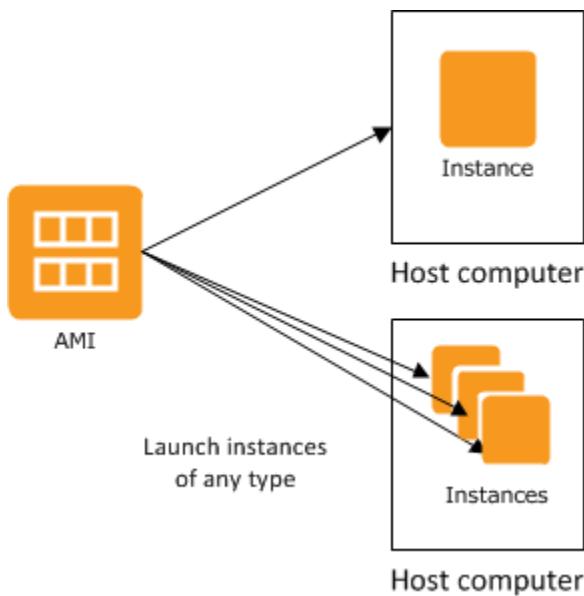

Each instance is backed by Amazon EBS or backed by instance store. Select an AMI based on which type of root volume you need. For more information, see [Storage for the root device \(p. 106\)](#).

Q. Can I remotely manage a fleet of EC2 instances and machines in my hybrid environment?

AWS Systems Manager enables you to remotely and securely manage the configuration of your Amazon EC2 instances, and your on-premises instances and virtual machines (VMs) in hybrid environments, including VMs from other cloud providers. For more information, see the [AWS Systems Manager User Guide](#).

Instances and AMIs

An *Amazon Machine Image (AMI)* is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch an *instance*, which is a copy of the AMI running as a virtual server in the cloud. You can launch multiple instances of an AMI, as shown in the following figure.

Your instances keep running until you stop, hibernate, or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

Instances

An instance is a virtual server in the cloud. Its configuration at launch is a copy of the AMI that you specified when you launched the instance.

You can launch different types of instances from a single AMI. An *instance type* essentially determines the hardware of the host computer used for your instance. Each instance type offers different compute and memory capabilities. Select an instance type based on the amount of memory and computing power that you need for the application or software that you plan to run on the instance. For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

After you launch an instance, it looks like a traditional host, and you can interact with it as you would any computer. You have complete control of your instances; you can use **sudo** to run commands that require root privileges.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see [How many instances can I run in Amazon EC2](#) in the Amazon EC2 General FAQ.

Storage for your instance

The root device for your instance contains the image used to boot the instance. The root device is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information, see [Amazon EC2 instance root device volume \(p. 1645\)](#).

Your instance may include local storage volumes, known as instance store volumes, which you can configure at launch time with block device mapping. For more information, see [Block device mappings \(p. 1654\)](#). After these volumes have been added to and mapped on your instance, they are available for you to mount and use. If your instance fails, or if your instance is stopped or terminated, the data on these volumes is lost; therefore, these volumes are best used for temporary data. To keep important data safe, you should use a replication strategy across multiple instances, or store your persistent data in Amazon S3 or Amazon EBS volumes. For more information, see [Storage \(p. 1346\)](#).

Security best practices

- Use AWS Identity and Access Management (IAM) to control access to your AWS resources, including your instances. You can create IAM users and groups under your AWS account, assign security credentials to each, and control the access that each has to resources and services in AWS. For more information, see [Identity and access management for Amazon EC2 \(p. 1240\)](#).
- Restrict access by only allowing trusted hosts or networks to access ports on your instance. For example, you can restrict SSH access by restricting incoming traffic on port 22. For more information, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).
- Review the rules in your security groups regularly, and ensure that you apply the principle of *least privilege*—only open up permissions that you require. You can also create different security groups to deal with instances that have different security requirements. Consider creating a bastion security group that allows external logins, and keep the remainder of your instances in a group that does not allow external logins.
- Disable password-based logins for instances launched from your AMI. Passwords can be found or cracked, and are a security risk. For more information, see [Disable password-based remote logins for root \(p. 136\)](#). For more information about sharing AMIs safely, see [Shared AMIs \(p. 122\)](#).

Stop and terminate instances

You can stop or terminate a running instance at any time.

Stop an instance

When an instance is stopped, the instance performs a normal shutdown, and then transitions to a stopped state. All of its Amazon EBS volumes remain attached, and you can start the instance again at a later time.

You are not charged for additional instance usage while the instance is in a stopped state. A minimum of one minute is charged for every transition from a stopped state to a running state. If the instance type was changed while the instance was stopped, you will be charged the rate for the new instance type after the instance is started. All of the associated Amazon EBS usage of your instance, including root device usage, is billed using typical Amazon EBS prices.

When an instance is in a stopped state, you can attach or detach Amazon EBS volumes. You can also create an AMI from the instance, and you can change the kernel, RAM disk, and instance type.

Terminate an instance

When an instance is terminated, the instance performs a normal shutdown. The root device volume is deleted by default, but any attached Amazon EBS volumes are preserved by default, determined by each volume's `deleteOnTermination` attribute setting. The instance itself is also deleted, and you can't start the instance again at a later time.

To prevent accidental termination, you can disable instance termination. If you do so, ensure that the `disableApiTermination` attribute is set to `true` for the instance. To control the behavior of an instance shutdown, such as `shutdown -h` in Linux or `shutdown` in Windows, set the `instanceInitiatedShutdownBehavior` instance attribute to `stop` or `terminate` as desired. Instances with Amazon EBS volumes for the root device default to `stop`, and instances with `instance-store` root devices are always terminated as the result of an instance shutdown.

For more information, see [Instance lifecycle \(p. 574\)](#).

Note

Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the [AWS Billing and Cost Management User Guide](#). For more information about Amazon EBS costs, see [Amazon EBS pricing](#).

AMIs

Amazon Web Services (AWS) publishes many [Amazon Machine Images \(AMIs\)](#) that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMI or AMIs; doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or a web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

All AMIs are categorized as either *backed by Amazon EBS*, which means that the root device for an instance launched from the AMI is an Amazon EBS volume, or *backed by instance store*, which means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

The description of an AMI indicates the type of root device (either `ebs` or `instance store`). This is important because there are significant differences in what you can do with each type of AMI. For more information about these differences, see [Storage for the root device \(p. 106\)](#).

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances. Existing instances launched from the AMI are not affected. Therefore, if you are also finished with the instances launched from these AMIs, you should terminate them.

Instance types

When you launch an instance, the *instance type* that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 provides each instance with a consistent and predictable amount of CPU capacity, regardless of its underlying hardware.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

Previous generation instances

Amazon Web Services offers previous generation instance types for users who have optimized their applications around them and have yet to upgrade. We encourage you to use current generation instance types to get the best performance, but we continue to support the following previous generation instance types. For more information about which current generation instance type would be a suitable upgrade, see [Previous Generation Instances](#).

Hardware specifications

For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, even after you make a decision, you can change the instance type later. For more information, see [Change the instance type \(p. 382\)](#).

Naming conventions

Instance type names combine the instance family, generation, and size. They can also indicate additional capabilities, such as:

- **a** – AMD processors
- **g** – AWS Graviton processors
- **i** – Intel processors

- **d** – Instance store volumes
- **n** – Network optimization
- **b** – Block storage optimization
- **e** – Extra storage or memory
- **z** – High frequency

Processor features

Intel processor features

Amazon EC2 instances that run on Intel processors may include the following features. Not all of the following processor features are supported by all instance types. For detailed information about which features are available for each instance type, see [Amazon EC2 Instance Types](#).

- **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.
- **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.
- **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.
- **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

The following instances support VNNI: M5n, R5n, M5dn, M5zn, R5b, R5dn, D3, and D3en. C5 and C5d instances support VNNI for only 12xlarge, 24xlarge, and metal instances.

Confusion may result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an instance running Ubuntu or Windows displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.

AMI virtualization types

The virtualization type of your instance is determined by the AMI that you use to launch it. Current generation instance types support hardware virtual machine (HVM) only. Some previous generation instance types support paravirtual (PV) and some AWS Regions support PV instances. For more information, see [Linux AMI virtualization types \(p. 108\)](#).

For best performance, we recommend that you use an HVM AMI. In addition, HVM AMIs are required to take advantage of enhanced networking. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.

Instances built on the Nitro System

The Nitro System is a collection of AWS-built hardware and software components that enable high performance, high availability, and high security. For more information, see [AWS Nitro System](#).

The Nitro System provides bare metal capabilities that eliminate virtualization overhead and support workloads that require full access to host hardware. Bare metal instances are well suited for the following:

- Workloads that require access to low-level hardware features (for example, Intel VT) that are not available or fully supported in virtualized environments
- Applications that require a non-virtualized environment for licensing or support

Nitro components

The following components are part of the Nitro System:

- Nitro card
 - Local NVMe storage volumes
 - Networking hardware support
 - Management
 - Monitoring
 - Security
- Nitro security chip, integrated into the motherboard
- Nitro hypervisor - A lightweight hypervisor that manages memory and CPU allocation and delivers performance that is indistinguishable from bare metal for most workloads.

Instance types

The following instances are built on the Nitro System:

- **Virtualized:** A1, C5, C5a, C5ad, C5d, C5n, C6a, C6g, C6gd, C6gn, C6i, D3, D3en, DL1, G4, G4ad, G5, G5g, Hpc6a, I3en, Im4gn, Inf1, Is4gen, M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6a, M6g, M6gd, M6i, p3dn.24xlarge, P4, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6g, R6gd, R6i, T3, T3a, T4g, u-3tb1.56xlarge, u-6tb1.56xlarge, u-6tb1.112xlarge, u-9tb1.112xlarge, u-12tb1.112xlarge, VT1, X2gd, and z1d

Networking and storage features

When you select an instance type, this determines the networking and storage features that are available. To describe an instance type, use the [describe-instance-types](#) command.

Networking features

- IPv6 is supported on all current generation instance types and the C3, R3, and I2 previous generation instance types.
- To maximize the networking and bandwidth performance of your instance type, you can do the following:
 - Launch supported instance types into a cluster placement group to optimize your instances for high performance computing (HPC) applications. Instances in a common cluster placement group can benefit from high-bandwidth, low-latency networking. For more information, see [Placement groups \(p. 1190\)](#).
 - Enable enhanced networking for supported current generation instance types to get significantly higher packet per second (PPS) performance, lower network jitter, and lower latencies. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).
 - Current generation instance types that are enabled for enhanced networking have the following networking performance attributes:
 - Traffic within the same Region over private IPv4 or IPv6 can support 5 Gbps for single-flow traffic and up to 25 Gbps for multi-flow traffic (depending on the instance type).
 - Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.
 - The maximum transmission unit (MTU) supported varies across instance types. All Amazon EC2 instance types support standard Ethernet V2 1500 MTU frames. All current generation instances support 9001 MTU, or jumbo frames, and some previous generation instances support them as well. For more information, see [Network maximum transmission unit \(MTU\) for your EC2 instance \(p. 1204\)](#).

Storage features

- Some instance types support EBS volumes and instance store volumes, while other instance types support only EBS volumes. Some instance types that support instance store volumes use solid state drives (SSD) to deliver very high random I/O performance. Some instance types support NVMe instance store volumes. Some instance types support NVMe EBS volumes. For more information, see [Amazon EBS and NVMe on Linux instances \(p. 1558\)](#) and [NVMe SSD volumes \(p. 1634\)](#).
- To obtain additional, dedicated capacity for Amazon EBS I/O, you can launch some instance types as EBS-optimized instances. Some instance types are EBS-optimized by default. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

Instance limits

There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types.

For more information about the default limits, see [How many instances can I run in Amazon EC2?](#)

For more information about viewing your current limits or requesting an increase in your current limits, see [Amazon EC2 service quotas \(p. 1706\)](#).

General purpose instances

General purpose instances provide a balance of compute, memory, and networking resources, and can be used for a wide range of workloads.

M5 and M5a instances

These instances provide an ideal cloud infrastructure, offering a balance of compute, memory, and networking resources for a broad range of applications that are deployed in the cloud. They are well-suited for the following:

- Small and midsize databases

- Data processing tasks that require additional memory
- Caching fleets
- Backend servers for SAP, Microsoft SharePoint, cluster computing, and other enterprise applications

For more information, see [Amazon EC2 M5 Instances](#).

Bare metal instances, such as `m5.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

M5zn

These instances are ideal for applications that benefit from extremely high single-thread performance, high throughput, and low latency networking. They are well-suited for the following:

- Gaming
- High performance computing
- Simulation modeling

For more information, see [Amazon EC2 M5 Instances](#).

Bare metal instances, such as `m5zn.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

M6g and M6gd instances

These instances are powered by AWS Graviton2 processors and deliver balanced compute, memory, and networking for a broad range a general purpose workloads. They are well suited for the following:

- Application servers
- Microservices
- Gaming servers
- Midsize data stores
- Caching fleets

Bare metal instances, such as `m6g.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 M6g Instances](#).

M6i instances

These instances are well suited for general-purpose workloads such as the following:

- Application servers and web servers
- Microservices
- High performance computing
- App development
- Small and midsize databases
- Caching fleets

Bare metal instances, such as `m6i.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 M6i Instances](#).

Mac1 instances

These instances are powered by Apple Mac mini computers. They provide up to 10 Gbps of network bandwidth and 8 Gbps EBS bandwidth through high-speed Thunderbolt 3 connections. They are well suited to develop, build, test, and sign applications for Apple devices, such as iPhone, iPad, iPod, Mac, Apple Watch, and Apple TV.

For more information, see [Amazon EC2 Mac instances \(p. 300\)](#).

T2, T3, T3a, and T4g instances

These instances provide a baseline level of CPU performance with the ability to burst to a higher level when required by your workload. An Unlimited instance can sustain high CPU performance for any period of time whenever required. For more information, see [Burstable performance instances \(p. 266\)](#). They are well-suited for the following:

- Websites and web applications
- Code repositories
- Development, build, test, and staging environments
- Microservices

For more information, see [Amazon EC2 T2 Instances](#), [Amazon EC2 T3 Instances](#), and [Amazon EC2 T4g Instances](#).

For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

For more information about specifying CPU options, see [Optimize CPU options \(p. 691\)](#).

Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some general purpose instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

Some general purpose instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see [Processor state control for your EC2 instance \(p. 678\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).

The following is a summary of network performance for general purpose instances that support enhanced networking.

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 1635\)](#).

Release notes

- M5, M5d, and T3 instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- M5a, M5ad, and T3a instances feature a 2.5 GHz AMD EPYC 7000 series processor.
- M5zn instances are powered by Intel Cascade Lake CPUs that deliver all-core turbo frequency of up to 4.5 GHz and up to 100 Gbps network bandwidth.
- M6g and M6gd instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- M6i instances feature third generation Intel Xeon Scalable processors (Ice Lake) and support the Intel Advanced Vector Extensions 512 (Intel AVX-512) instruction set.
- Mac1 instances feature a 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processor.
- T4g instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- Instances built on the [Nitro System \(p. 247\)](#), M4, t2.large and larger, t3.large and larger, and t3a.large and larger instance types require 64-bit HVM AMIs. They have high-memory, and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the [Nitro System \(p. 247\)](#) have the following requirements:
 - [NVMe drivers \(p. 1558\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1125\)](#) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Instances with an [AWS Graviton Processor](#) have the following requirements:
 - Use an AMI for the 64-bit Arm architecture.
 - Support booting through UEFI with ACPI tables and support ACPI hot-plug of PCI devices.

The following Linux AMIs meet these requirements:

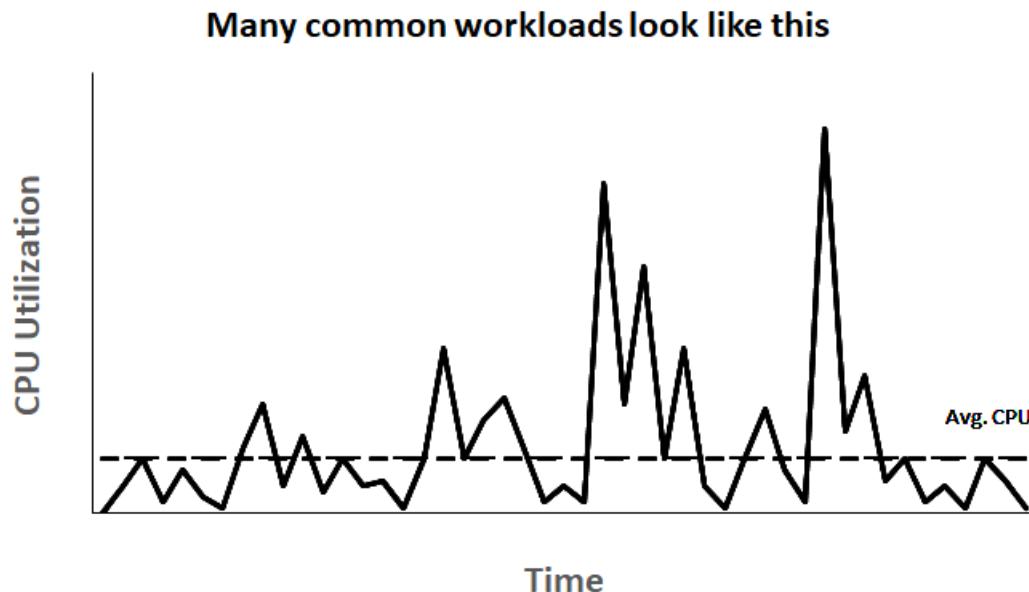

- Amazon Linux 2 (64-bit Arm)
- Ubuntu 16.04 or later (64-bit Arm)
- Red Hat Enterprise Linux 8.0 or later (64-bit Arm)
- SUSE Linux Enterprise Server 15 or later (64-bit Arm)
- Debian 10 or later (64-bit Arm)
- To get the best performance from your M6i instances, ensure that they have ENA driver version 2.2.9 or later. Using an ENA driver earlier than version 1.2 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - Amazon Linux 2 with kernel 4.14.186
 - Ubuntu 20.04 with kernel 5.4.0-1025-aws
 - Red Hat Enterprise Linux 8.3 with kernel 4.18.0-240.1.1.el8_3.ARCH
 - SUSE Linux Enterprise Server 15 SP2 with kernel 5.3.18-24.15.1
- Amazon EC2 Mac instances support macOS Mojave (version 10.14), macOS Catalina (version 10.15), and macOS Big Sur (version 11).
- Instances built on the Nitro System support a maximum of 28 attachments, including network interfaces, EBS volumes, and NVMe instance store volumes. For more information, see [Nitro System volume limits \(p. 1644\)](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- Instances built on the Nitro System should have `system-logind` or `acpid` installed to support clean shutdown through API requests.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Burstable performance instances

Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.

These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute, memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory. The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

Note

This topic describes burstable CPU. For information about burstable network performance, see [Amazon EC2 instance network bandwidth \(p. 1122\)](#).

EC2 burstable instance types

The EC2 burstable instances consist of T4g, T3a and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based [AWS Graviton2](#) processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

Type	Description	Processor family
Latest generation		
T4g	Lowest cost EC2 instance type with up to 40% higher price/ performance and 20% lower costs vs T3	AWS Graviton2 processors with Arm Neoverse N1 cores
T3a	Lowest cost x86-based instances with 10% lower costs vs T3 instances	AMD 1st gen EPYC processors
T3	Best peak price/performance for x86 workloads with up to 30% lower price/performance vs previous generation T2 instances	Intel Xeon Scalable (Skylake, Cascade Lake processors)
Previous generation		
T2	Previous generation burstable instances	Intel Xeon processors

For information about instance pricing and additional specifications, see [Amazon EC2 Pricing](#) and [Amazon EC2 Instance Types](#). For information about burstable network performance, see [Amazon EC2 instance network bandwidth \(p. 1122\)](#).

If your account is less than 12 months old, you can use a `t2.micro` instance for free (or a `t3.micro` instance in Regions where `t2.micro` is unavailable) within certain usage limits. For more information, see [AWS Free Tier](#).

Supported purchasing options for T instances

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Dedicated Hosts (T3 only, in standard mode only)
- Spot Instances

For more information, see [Instance purchasing options \(p. 390\)](#).

Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a `t3.micro` or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.
- Enable [AWS Compute Optimizer](#) for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be upsized to improve performance or downsized for cost savings.
- For additional requirements, see [Release notes \(p. 264\)](#).

Key concepts and definitions for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credits when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

- If the CPU utilization is below baseline, then credits earned are greater than credits spent.
- If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
- If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, then the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.

In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see [Get statistics for a specific instance \(p. 990\)](#).

CPU credit

A unit of vCPU-time.

Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.

1 CPU credit = 1 vCPU * 50% utilization * 2 minutes

1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:

If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = $6 - 2 \text{ vCPUs} * 2\% \text{ CPU utilization} * 60 \text{ minutes} = 6 - 2.4 = 3.6$ accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.

Example:

For t3.nano, the credit accrual limit = $24 * 6 = 144$ credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
Latest generation			
T4g	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3a	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3	Earned credits, Accrued credits, Spent	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
	credits, Surplus credits (Unlimited mode only)		
Previous generation			
T2	Earned credits, Accrued credits, Spent credits, Launch credits (Standard mode only), Surplus credits (Unlimited mode only)	Standard (default), Unlimited	0 days (credits are lost when an instance stops)

Note

Unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don't have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a t3.large instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see [Baseline utilization \(p. 274\)](#).

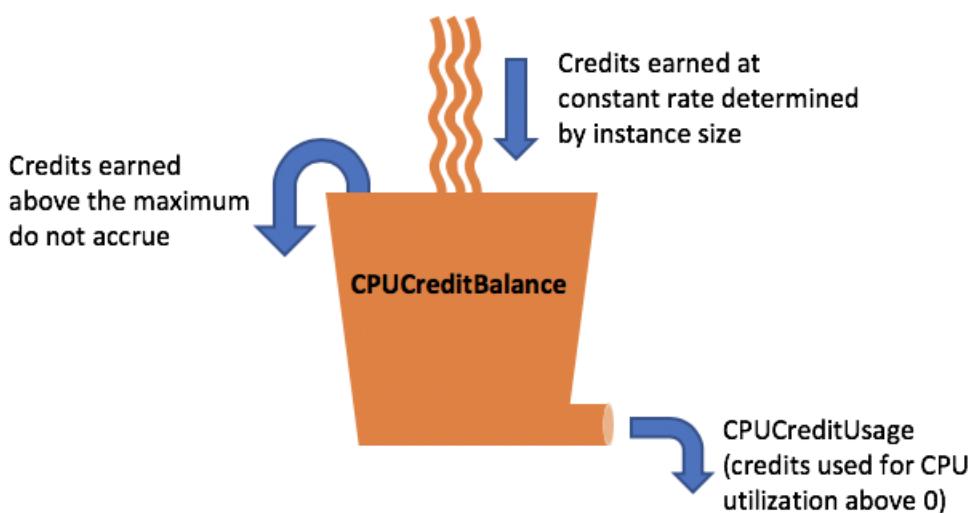

*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 and T4g instances.

CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a `t3.nano` earns six credits per hour, while a `t3.small` earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.

CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned credits that exceed the limit.

The CPU credit balance limit differs for each instance size. For example, a `t3.micro` instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see [Launch credits \(p. 282\)](#).

T4g, T3a and T3 instances do not earn launch credits. These instances launch as `unlimited` by default, and therefore can burst immediately upon start without any launch credits. T3 instances launched on a Dedicated Host launch as `standard` by default; `de>unlimited` mode is not supported for T3 instances on a Dedicated Host.

Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T4g, T3a and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see `CPUCreditBalance` in the [CloudWatch metrics table \(p. 297\)](#).

Baseline utilization

The *baseline utilization* is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as *the baseline*.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

$$(\text{number of credits earned}/\text{number of vCPUs})/60 \text{ minutes} = \% \text{ baseline utilization}$$

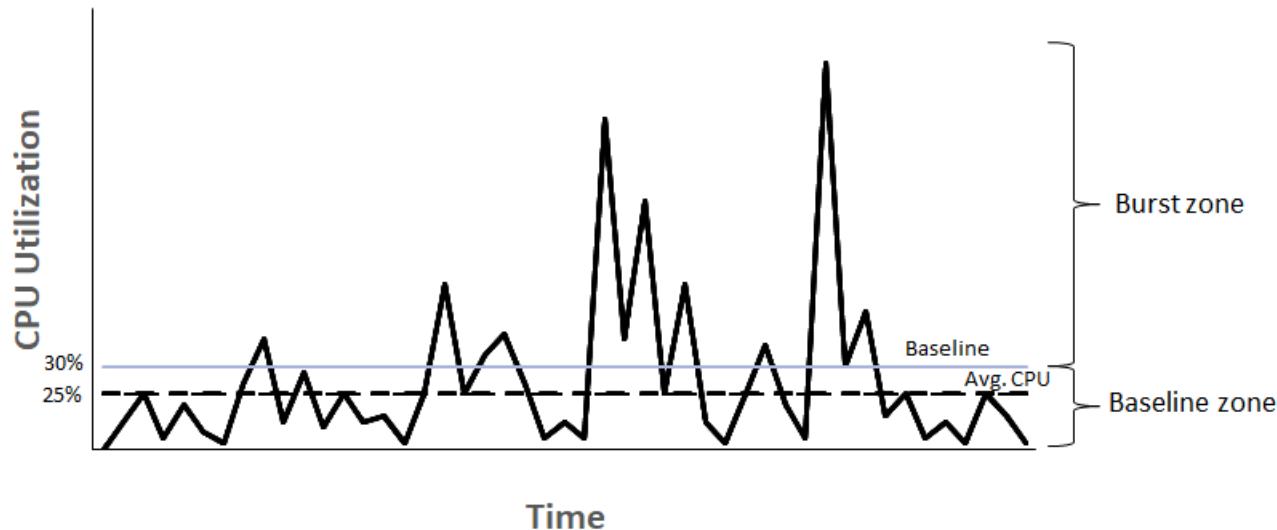

For example, a t3.nano instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5%, which is calculated as follows:

$$(6 \text{ credits earned}/2 \text{ vCPUs})/60 \text{ minutes} = 5\% \text{ baseline utilization}$$

A t3.xlarge instance, with 4 vCPUs, earns 96 credits per hour, resulting in a baseline utilization of 40% ($(96/4)/60$).

The following graph provides an example of a t3.large with an average CPU utilization below the baseline.

Example of t3.large

Unlimited mode for burstable performance instances

A burstable performance instance configured as `unlimited` can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as `unlimited` provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see [Amazon EC2 pricing](#) and [T2/T3/T4 Unlimited Mode Pricing](#).

If you use a t2.micro or t3.micro instance under the [AWS Free Tier](#) offer and use it in `unlimited` mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the [baseline utilization](#) (p. 274) of the instance.

T4g, T3a and T3 instances launch as [unlimited](#) by default. If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as [unlimited](#) and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in [standard](#) (p. 281) mode to avoid paying higher costs. For more information, see [Surplus credits can incur charges](#) (p. 278) and [Burstable performance instances](#) (p. 498).

Note

T3 instances launched on a Dedicated Host launch as [standard](#) by default; [unlimited](#) mode is not supported for T3 instances on a Dedicated Host.

[Unlimited mode concepts](#)

The [unlimited](#) mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set [unlimited](#) as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

[How Unlimited burstable performance instances work](#)

If a burstable performance instance configured as [unlimited](#) depletes its CPU credit balance, it can spend [surplus](#) credits to burst beyond the [baseline](#) (p. 274). When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a [flat additional rate](#) per vCPU-hour.

The following graph shows the CPU usage of a t3.large. The baseline CPU utilization for a t3.large is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a [flat additional rate](#) per vCPU-hour.

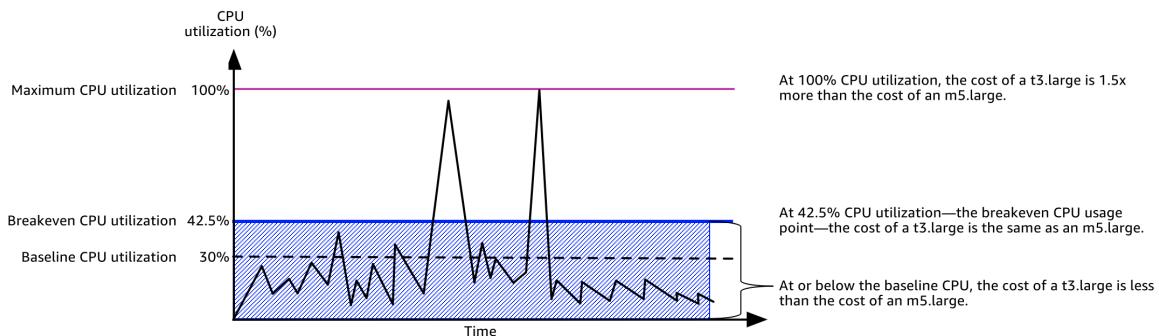

For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the [credit table \(p. 271\)](#).

When to use unlimited mode versus fixed CPU

When determining whether you should use a burstable performance instance in **unlimited mode**, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:

- If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a burstable performance instance in **unlimited mode** so that you can benefit from the lower price of a burstable performance instance while getting the same performance as a fixed performance instance.
- If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable performance instance will cost more than the equivalently-sized fixed performance instance. If a T3 instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a t3.large costs the same as an m5.large. The breakeven CPU usage point for a t3.large is 42.5%. If the average CPU usage is at 42.5%, the cost of running the t3.large is the same as an m5.large, and is more expensive if the average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can benefit from the lower price of the t3.large while getting the same performance as an m5.large.

The following table shows how to calculate the breakeven CPU usage threshold so that you can determine when it's less expensive to use a burstable performance instance in `unlimited` mode or a fixed performance instance. The columns in the table are labeled A through K.

Instance type	vCPUs	T3 price*/hour	M5 price*/hour	Price difference	T3 baseline utilization per vCPU (%)	Charge per vCPU hour for surplus credits	Charge per vCPU minute	Additional burst minutes available	Additional CPU % available	Breakeven CPU %
A	B	C	D	E = D - C	F	G	H = G / 60	I = E / H	J = (I / 60) / B	K = F + J
t3.large	2	\$0.0835	\$0.096	\$0.0125	30%	\$0.05	\$0.000833	15	12.5%	42.5%

* Price is based on us-east-1 and Linux OS.

The table provides the following information:

- Column A shows the instance type, `t3.large`.
- Column B shows the number of vCPUs for the `t3.large`.
- Column C shows the price of a `t3.large` per hour.
- Column D shows the price of an `m5.large` per hour.
- Column E shows the price difference between the `t3.large` and the `m5.large`.
- Column F shows the baseline utilization per vCPU of the `t3.large`, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.
- Column G shows the [flat additional rate](#) per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column H shows the [flat additional rate](#) per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column I shows the number of additional minutes that the `t3.large` can burst per hour at 100% CPU while paying the same price per hour as an `m5.large`.
- Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an `m5.large`.
- Column K shows the breakeven CPU usage (in %) that the `t3.large` can burst without paying more than the `m5.large`. Anything above this, and the `t3.large` costs more than the `m5.large`.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

T3 instance type	Breakeven CPU usage (in %) for T3 compared to M5
<code>t3.large</code>	42.5%
<code>t3.xlarge</code>	52.5%
<code>t3.2xlarge</code>	52.5%

Surplus credits can incur charges

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a [maximum number of credits \(p. 271\)](#) in a 24-hour period (for example, a `t3.micro` instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see [T2/T3/T4g Unlimited Mode Pricing](#).

Surplus credits that were spent earlier are charged when any of the following occurs:

- The spent surplus credits exceed the [maximum number of credits \(p. 271\)](#) the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.
- The instance is stopped or terminated.
- The instance is switched from `unlimited` to `standard`.

Spent surplus credits are tracked by the CloudWatch metric `CPUSurplusCreditBalance`. Surplus credits that are charged are tracked by the CloudWatch metric `CPUSurplusCreditsCharged`. For more information, see [Additional CloudWatch metrics for burstable performance instances \(p. 296\)](#).

No launch credits for T2 Unlimited instances

T2 Standard instances receive [launch credits \(p. 282\)](#), but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.

If a T2 instance is switched from `standard` to `unlimited`, any accrued launch credits are removed from the `CPUCreditBalance` before the remaining `CPUCreditBalance` is carried over.

T4g, T3a and T3 instances never receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Enable unlimited mode

You can switch from `unlimited` to `standard`, and from `standard` to `unlimited`, at any time on a running or stopped instance. For more information, see [Launch a burstable performance instance as Unlimited or Standard \(p. 291\)](#) and [Modify the credit specification of a burstable performance instance \(p. 294\)](#).

You can set `unlimited` as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see [Set the default credit specification for the account \(p. 295\)](#).

You can check whether your burstable performance instance is configured as `unlimited` or `standard` using the Amazon EC2 console or the AWS CLI. For more information, see [View the credit specification of a burstable performance instance \(p. 293\)](#) and [View the default credit specification \(p. 296\)](#).

What happens to credits when switching between Unlimited and Standard

`CPUCreditBalance` is a CloudWatch metric that tracks the number of credits accrued by an instance. `CPUSurplusCreditBalance` is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as `unlimited` to `standard`, the following occurs:

- The `CPUCreditBalance` value remains unchanged and is carried over.
- The `CPUSurplusCreditBalance` value is immediately charged.

When a `standard` instance is switched to `unlimited`, the following occurs:

- The `CPUCreditBalance` value containing accrued earned credits is carried over.
- For T2 Standard instances, any launch credits are removed from the `CPUCreditBalance` value, and the remaining `CPUCreditBalance` value containing accrued earned credits is carried over.

Monitor credit usage

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see [Monitor your CPU credits \(p. 296\)](#).

Unlimited mode examples

The following examples explain credit use for instances that are configured as `unlimited`.

Examples

- [Example 1: Explain credit use with T3 Unlimited \(p. 279\)](#)
- [Example 2: Explain credit use with T2 Unlimited \(p. 280\)](#)

Example 1: Explain credit use with T3 Unlimited

In this example, you see the CPU utilization of a `t3.nano` instance launched as `unlimited`, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A `t3.nano` instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric `CPUCreditBalance`), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a `t3.nano` instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its `CPUCreditBalance`. The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as `unlimited` and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the `CPUCreditBalance` value cannot exceed its maximum of 144 credits.

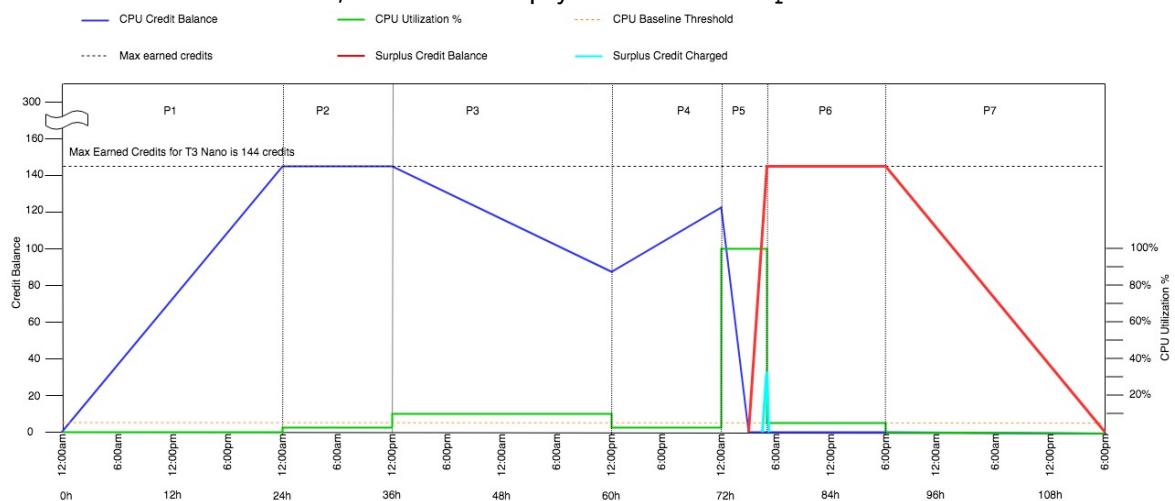

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the `CPUCreditBalance` value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the `CPUCreditBalance` value increases to 122 credits.

P5 – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire CPUCreditBalance of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period ($570 - 122 = 448$). When the CPUSurplusCreditBalance value reaches 144 CPU credits (the maximum a t3.nano instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits ($448 - 144 = 304$), which results in a small additional charge at the end of the hour for 304 credits.

P6 – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the CPUSurplusCreditBalance. The CPUSurplusCreditBalance value remains at 144 credits.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the CPUSurplusCreditBalance.

Example 2: Explain credit use with T2 Unlimited

In this example, you see the CPU utilization of a t2.nano instance launched as `unlimited`, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

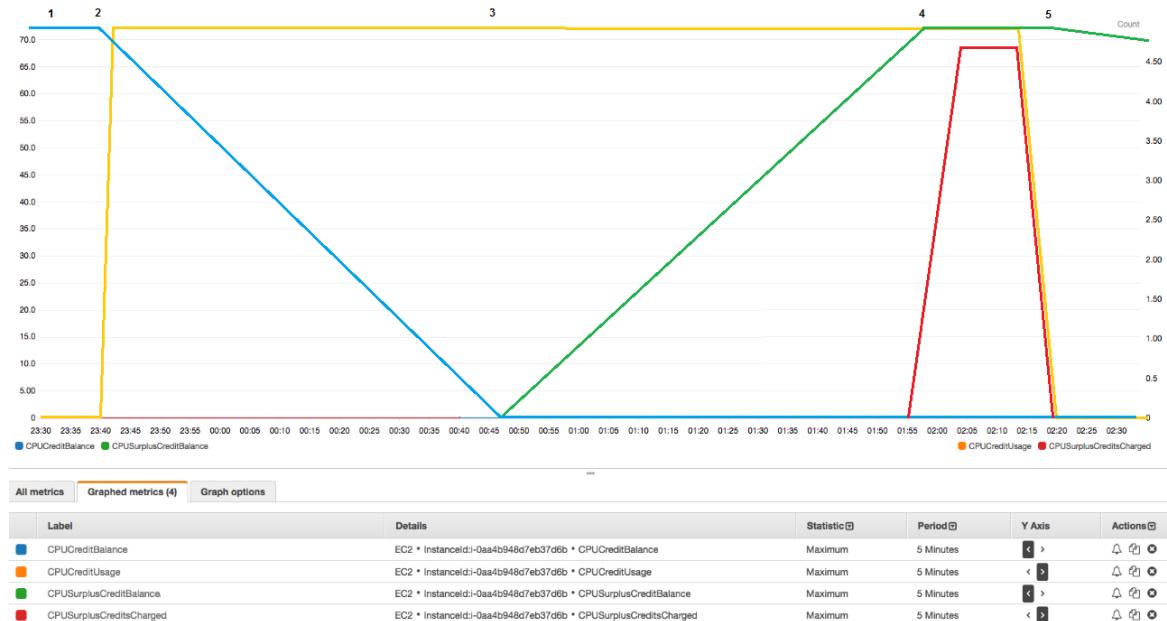

A t2.nano instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric `CPUCreditBalance`), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a t2.nano instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its `CPUCreditBalance`. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

- 1 – In the first 10 minutes, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value remains at its maximum of 72.
- 2 – At 23:40, as CPU utilization increases, the instance spends CPU credits and the `CPUCreditBalance` value decreases.
- 3 – At around 00:47, the instance depletes its entire `CPUCreditBalance`, and starts to spend surplus credits to sustain high CPU utilization.
- 4 – Surplus credits are spent until 01:55, when the `CPUSurplusCreditBalance` value reaches 72 CPU credits. This is equal to the maximum a t2.nano instance can earn in a 24-hour period. Any surplus

credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.

5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the `CPUSurplusCreditBalance`. After the `CPUSurplusCreditBalance` value reduces to 0, the instance starts to accrue earned credits in its `CPUCreditBalance` at 0.25 credits every 5 minutes.

Calculating the bill

Surplus credits cost \$0.05 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours.

Additional charges for this instance are $0.42 \text{ vCPU-hours} \times \$0.05/\text{vCPU-hour} = \0.021 , rounded to \$0.02.

Here is the month-end bill for this T2 Unlimited instance:

Amazon Elastic Compute Cloud running Linux/UNIX			
\$0.0058 per On Demand Linux t2.nano Instance Hour	720.000 Hrs	\$4.18	
Amazon Elastic Compute Cloud T2 CPU Credits			
\$0.05 per vCPU-Hour of T2 CPU credits	0.420 vCPU-Hours	\$0.02	

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

Standard mode for burstable performance instances

A burstable performance instance configured as standard is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see [Key concepts and definitions for burstable performance instances \(p. 268\)](#).

Standard mode concepts

The standard mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set standard as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How standard burstable performance instances work

When a burstable performance instance configured as standard is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T4g, T3a and T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of CPU credits: *earned credits* and *launch credits*. When a T2 Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore, to provide a good startup experience, it receives launch credits at start, which it spends first while it accrues earned credits.

T4g, T3a and T3 instances do not receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start. For example, a t2.micro instance has one vCPU and gets 30 launch credits, while a t2.xlarge instance has four vCPUs and gets 120 launch credits. Launch credits are designed to provide a good startup experience to allow instances to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU credit balance, but do not count towards the CPU credit balance limit. For example, a t2.micro instance has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours, its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit.

However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more information about the CPU credit balance limit for each instance size, see the [credit table \(p. 271\)](#).

The following table lists the initial CPU credit allocation received at launch or start, and the number of vCPUs.

Instance type	Launch credits	vCPUs
t1.micro	15	1
t2.nano	30	1
t2.micro	30	1
t2.small	30	1
t2.medium	60	2
t2.large	60	2
t2.xlarge	120	4
t2.2xlarge	240	8

Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. For example, the limit is reached when one instance is stopped and started 100 times within a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your usage.

Tip

To ensure that your workloads always get the performance they need, switch to [Unlimited mode for burstable performance instances \(p. 274\)](#) or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

	Launch credits	Earned credits
Credit earn rate	T2 Standard instances get 30 launch credits per vCPU at launch or start. If a T2 instance is switched from unlimited to standard, it does not get launch credits at the time of switching.	Each T2 instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. For more information about the number of CPU credits earned per instance size, see the credit table (p. 271) .
Credit earn limit	The limit for receiving launch credits is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. New accounts may have a lower limit, which increases over time based on your usage.	A T2 instance cannot accrue more credits than the CPU credit balance limit. If the CPU credit balance has reached its limit, any credits that are earned after the limit is reached are discarded. Launch credits do not count towards the limit. For more information about the CPU credit balance

	Launch credits	Earned credits
		limit for each T2 instance size, see the credit table (p. 271) .
Credit use	Launch credits are spent first, before earned credits.	Earned credits are spent only after all launch credits are spent.
Credit expiration	When a T2 Standard instance is running, launch credits do not expire. When a T2 Standard instance stops or is switched to T2 Unlimited, all launch credits are lost.	When a T2 instance is running, earned credits that have accrued do not expire. When the T2 instance stops, all accrued earned credits are lost.

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric `CPUCreditBalance`. For more information, see `CPUCreditBalance` in the [CloudWatch metrics table \(p. 297\)](#).

Standard mode examples

The following examples explain credit use when instances are configured as `standard`.

Examples

- [Example 1: Explain credit use with T3 Standard \(p. 284\)](#)
- [Example 2: Explain credit use with T2 Standard \(p. 285\)](#)

Example 1: Explain credit use with T3 Standard

In this example, you see how a `t3.nano` instance launched as `standard` earns, accrues, and spends *earned* credits. You see how the credit balance reflects the accrued *earned* credits.

A running `t3.nano` instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table \(p. 271\)](#).

You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance reaches its limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as `standard` and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the `CPUCreditBalance` value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

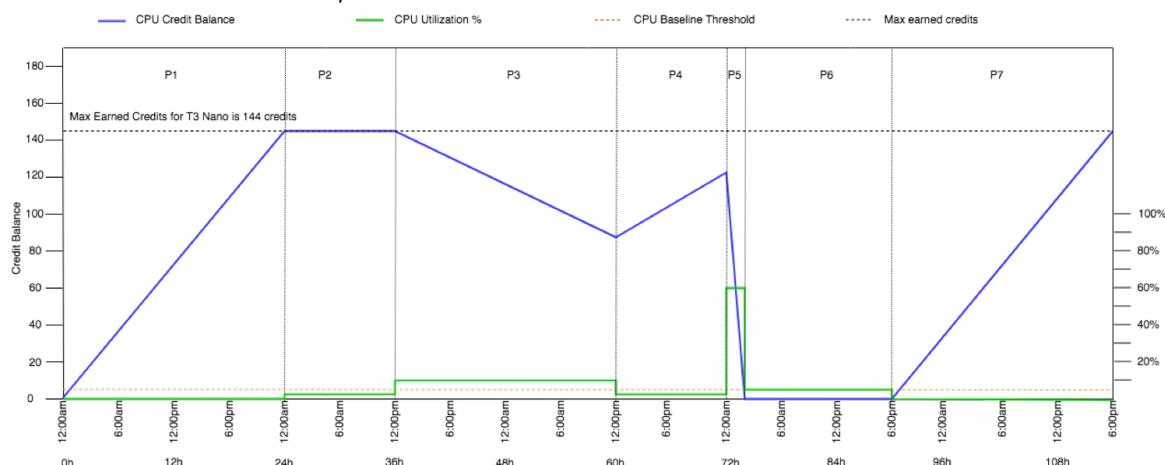

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the `CPUCreditBalance` value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the `CPUCreditBalance` value increases to 122 credits.

P5 – For the next two hours, the instance bursts at 100% CPU utilization, and depletes its entire `CPUCreditBalance` value of 122 credits. At the end of this period, with the `CPUCreditBalance` at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

P6 – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The `CPUCreditBalance` value remains at 0.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its `CPUCreditBalance`.

Example 2: Explain credit use with T2 Standard

In this example, you see how a `t2.nano` instance launched as standard earns, accrues, and spends *launch* and *earned* credits. You see how the credit balance reflects not only accrued *earned* credits, but also accrued *launch* credits.

A `t2.nano` instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table \(p. 271\)](#). For more information about limits, see [Launch credit limits \(p. 283\)](#).

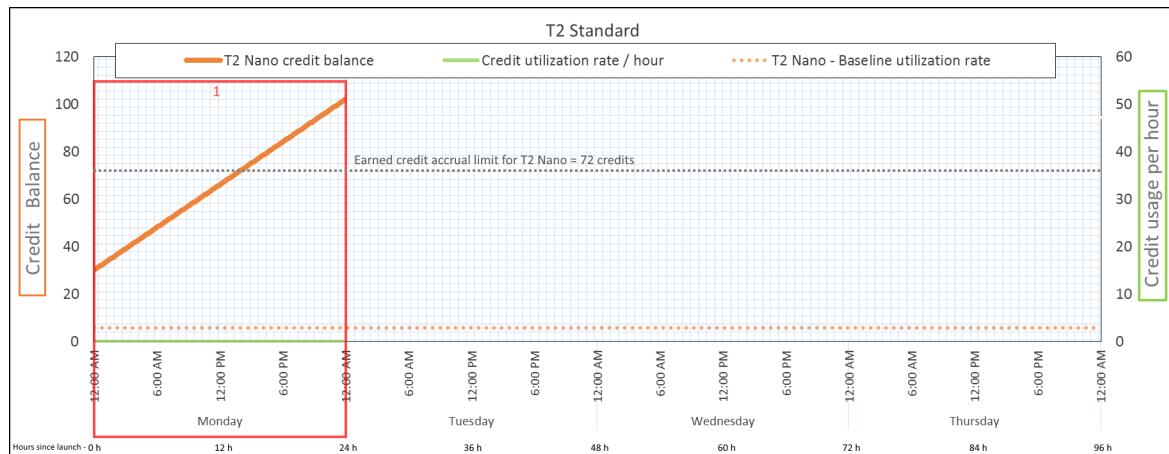

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

Period 1: 1 – 24 hours

At 0 hours on the graph, the T2 instance is launched as standard and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance.

At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	0 credits per 24 hours
Credit Balance	102 credits (30 launch credits + 72 earned credits)

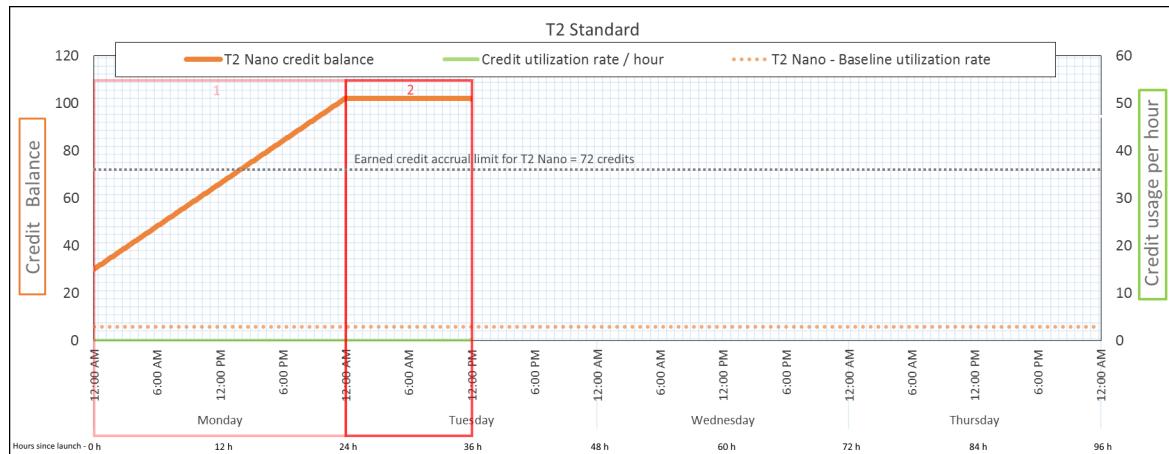

Conclusion

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.

Period 2: 25 – 36 hours

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.

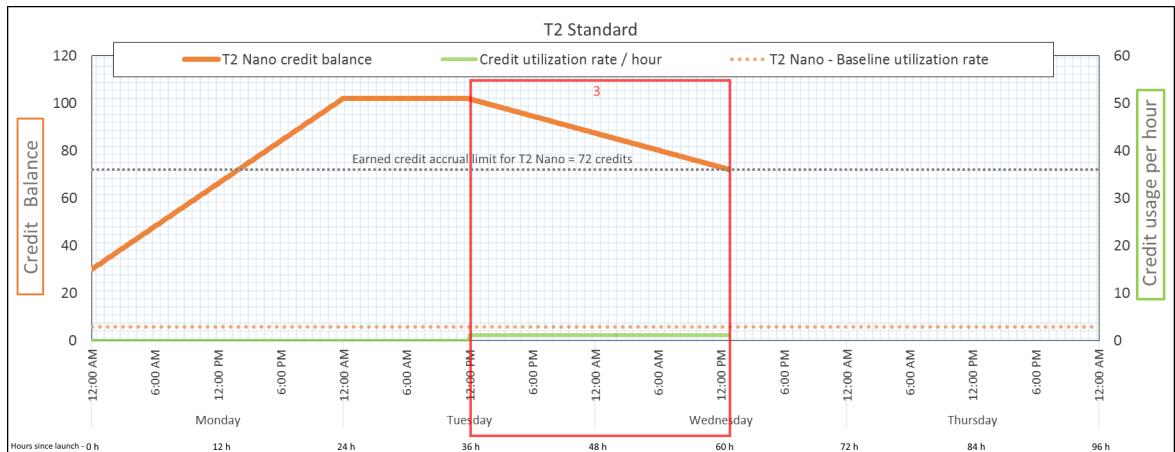

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours (3 credits per hour)
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	102 credits (30 launch credits + 72 earned credits) —balance is unchanged

Conclusion

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.

Period 3: 37 – 61 hours

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued *launch* credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (30 launch credits were spent; 72 earned credits remain unspent)

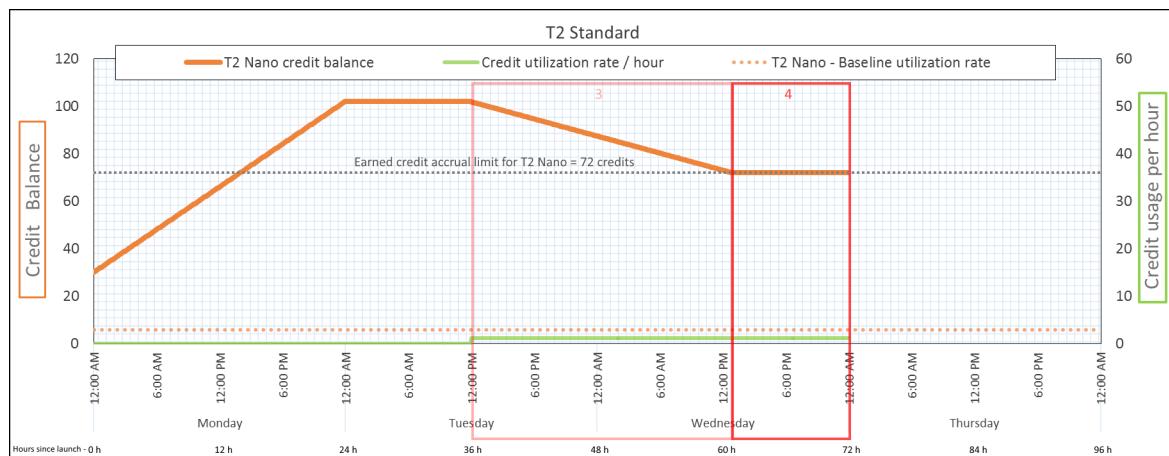

Conclusion

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.

Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.

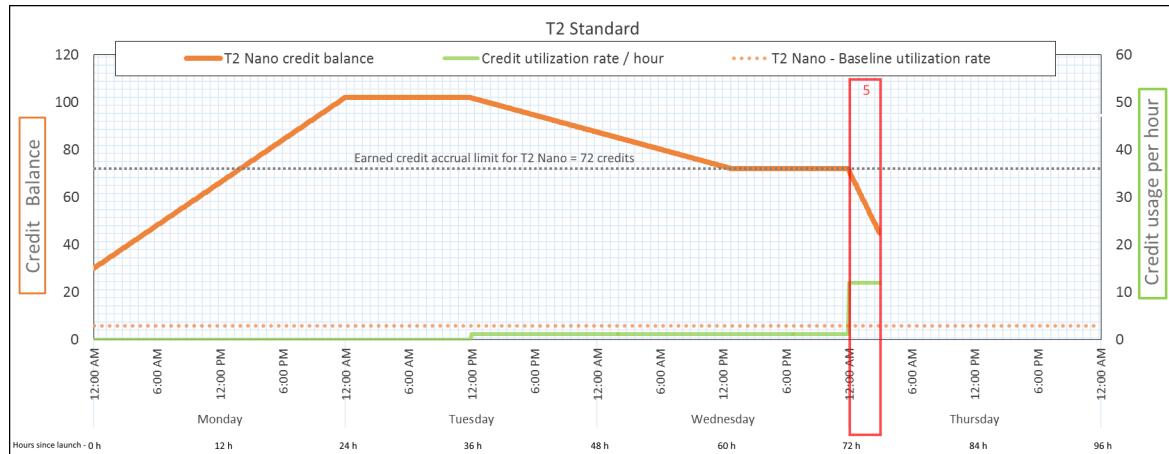

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—13.2 credits over 11 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	43.2 credits per 24 hours (60% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)—balance is at its limit

Conclusion

After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

Period 5: 73 – 75 hours

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.

Credit Spend Rate	288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate)—36 credits over 3 hours
Credit Earn Rate	72 credits per 24 hours (9 credits over 3 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)

Conclusion

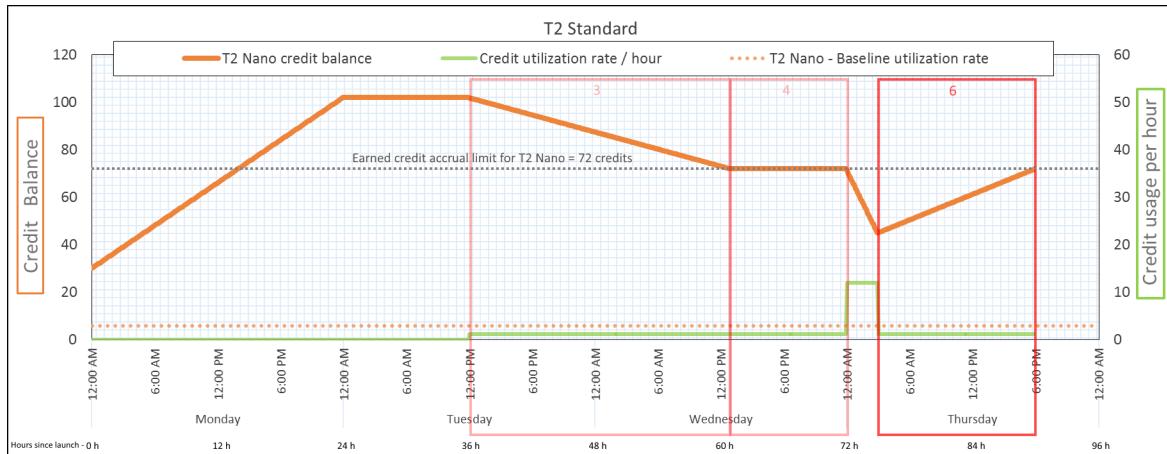

If an instance spends more credits than it earns, its credit balance decreases.

Period 6: 76 – 90 hours

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours
Credit Earn Rate	72 credits per 24 hours (45 credits over 15 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate 28.8/24 + earn rate 72/24)

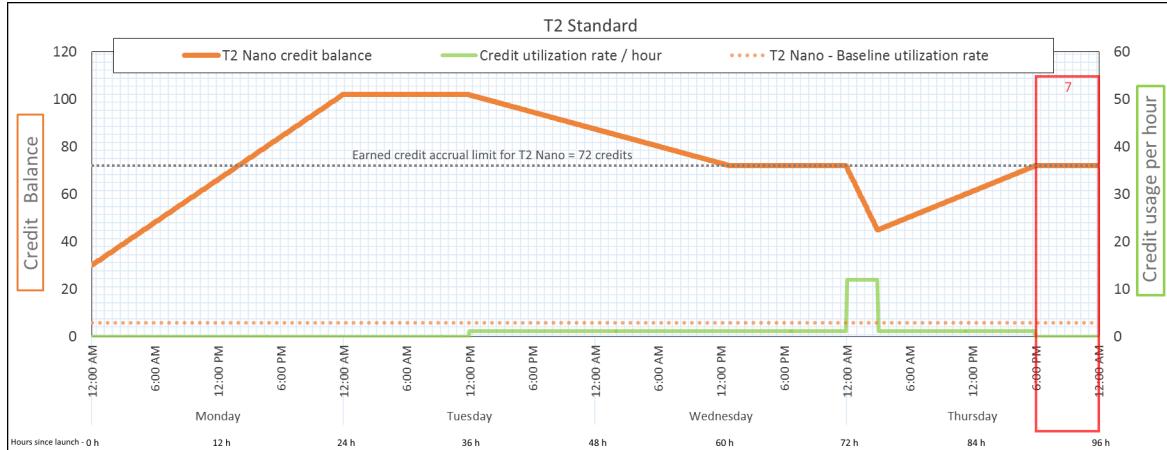

Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)

Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the [credit table \(p. 271\)](#).

Work with burstable performance instances

The steps for launching, monitoring, and modifying these instances are similar. The key difference is the default credit specification when they launch. If you do not change the default credit specification, the default is that:

- T4g, T3a and T3 instances launch as `unlimited`
- T3 instances on a Dedicated Host launch as `standard`
- T2 instances launch as `standard`

Contents

- [Launch a burstable performance instance as Unlimited or Standard \(p. 291\)](#)
- [Use an Auto Scaling group to launch a burstable performance instance as Unlimited \(p. 292\)](#)
- [View the credit specification of a burstable performance instance \(p. 293\)](#)
- [Modify the credit specification of a burstable performance instance \(p. 294\)](#)
- [Set the default credit specification for the account \(p. 295\)](#)
- [View the default credit specification \(p. 296\)](#)

Launch a burstable performance instance as Unlimited or Standard

You can launch your instances as `unlimited` or `standard` using the Amazon EC2 console, an AWS SDK, a command line tool, or with an Auto Scaling group. For more information, see [Use an Auto Scaling group to launch a burstable performance instance as Unlimited \(p. 292\)](#).

Requirements

- You must launch your instances using an Amazon EBS volume as the root device. For more information, see [Amazon EC2 instance root device volume \(p. 1645\)](#).
- For more information about AMI and driver requirements for these instances, see [Release notes \(p. 264\)](#).

To launch a burstable performance instance as Unlimited or Standard (console)

1. Follow the [Launch an instance using the Launch Instance Wizard \(p. 580\)](#) procedure.
2. On the **Choose an Instance Type** page, select an instance type, and choose **Next: Configure Instance Details**.

3. Choose a credit specification.
 - a. To launch a T4g, T3a and T3 instance as standard, clear **Unlimited**.
 - b. To launch a T2 instance as unlimited, select **Unlimited**.
4. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

To launch a burstable performance instance as Unlimited or Standard (AWS CLI)

Use the `run-instances` command to launch your instances. Specify the credit specification using the `--credit-specification CpuCredits=` parameter. Valid credit specifications are `unlimited` and `standard`.

- For T4g, T3a and T3, if you do not include the `--credit-specification` parameter, the instance launches as `unlimited` by default.
- For T2, if you do not include the `--credit-specification` parameter, the instance launches as `standard` by default.

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t3.micro --key-name MyKeyPair --credit-specification "CpuCredits=unlimited"
```

Use an Auto Scaling group to launch a burstable performance instance as Unlimited

When burstable performance instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend that you configure your instances as `unlimited`. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

Create a launch template

You must use a *launch template* for launching instances as `unlimited` in an Auto Scaling group. A launch configuration does not support launching instances as `unlimited`.

Note

`unlimited` mode is not supported for T3 instances that are launched on a Dedicated Host.

To create a launch template that launches instances as Unlimited (console)

1. Follow the [Creating a Launch Template for an Auto Scaling Group](#) procedure.
2. In **Launch template contents**, for **Instance type**, choose an instance size.
3. To launch instances as `unlimited` in an Auto Scaling group, under **Advanced details**, for **Credit specification**, choose **Unlimited**.
4. When you've finished defining the launch template parameters, choose **Create launch template**. For more information, see [Creating a Launch Template for an Auto Scaling Group](#) in the *Amazon EC2 Auto Scaling User Guide*.

To create a launch template that launches instances as Unlimited (AWS CLI)

Use the `create-launch-template` command and specify `unlimited` as the credit specification.

- For T4g, T3a and T3, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as `unlimited` by default.

- For T2, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as standard by default.

```
aws ec2 create-launch-template --launch-template-name MyLaunchTemplate
--version-description FirstVersion --launch-template-data
ImageId=ami-8c1be5f6,InstanceType=t3.medium,CreditSpecification={CpuCredits=unlimited}
```

Associate an Auto Scaling group with a launch template

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

To create an Auto Scaling group using a launch template (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**, **Create Auto Scaling group**.
4. Choose **Launch Template**, select your launch template, and then choose **Next Step**.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the **Review page**, choose **Create Auto Scaling group**. For more information, see [Creating an Auto Scaling Group Using a Launch Template](#) in the *Amazon EC2 Auto Scaling User Guide*.

To create an Auto Scaling group using a launch template (AWS CLI)

Use the `create-auto-scaling-group` AWS CLI command and specify the `--launch-template` parameter.

To add a launch template to an existing Auto Scaling group (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**.
4. From the Auto Scaling group list, select an Auto Scaling group, and choose **Actions**, **Edit**.
5. On the **Details** tab, for **Launch Template**, choose a launch template, and then choose **Save**.

To add a launch template to an existing Auto Scaling group (AWS CLI)

Use the `update-auto-scaling-group` AWS CLI command and specify the `--launch-template` parameter.

View the credit specification of a burstable performance instance

You can view the credit specification (unlimited or standard) of a running or stopped instance.

New console

To view the credit specification of a burstable instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance.

4. Choose **Details** and view the **Credit specification** field. The value is either **unlimited** or **standard**.

Old console

To view the credit specification of a burstable instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Description** and view the **T2/T3 Unlimited** field.
 - If the value is **Enabled**, then your instance is configured as **unlimited**.
 - If the value is **Disabled**, then your instance is configured as **standard**.

To describe the credit specification of a burstable performance instance (AWS CLI)

Use the `describe-instance-credit-specifications` command. If you do not specify one or more instance IDs, all instances with the credit specification of **unlimited** are returned, as well as instances that were previously configured with the **unlimited** credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as **unlimited**, Amazon EC2 returns the M4 instance.

Example

```
aws ec2 describe-instance-credit-specifications --instance-id i-1234567890abcdef0
```

The following is example output:

```
{  
    "InstanceCreditSpecifications": [  
        {  
            "InstanceId": "i-1234567890abcdef0",  
            "CpuCredits": "unlimited"  
        }  
    ]  
}
```

Modify the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped instance at any time between **unlimited** and **standard**.

New console

To modify the credit specification of a burstable performance instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose **Actions, Instance settings, Change credit specification**. This option is enabled only if you selected a burstable performance instance.
5. To change the credit specification to **unlimited**, select the check box next to the instance ID. To change the credit specification to **standard**, clear the check box next to the instance ID.

Old console

To modify the credit specification of a burstable performance instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose **Actions, Instance Settings, Change T2/T3 Unlimited**. This option is enabled only if you selected a burstable performance instance.
5. The current credit specification appears in parentheses after the instance ID. To change the credit specification to unlimited, choose **Enable**. To change the credit specification to standard, choose **Disable**.

To modify the credit specification of a burstable performance instance (AWS CLI)

Use the **modify-instance-credit-specification** command. Specify the instance and its credit specification using the **--instance-credit-specification** parameter. Valid credit specifications are **unlimited** and **standard**.

Example

```
aws ec2 modify-instance-credit-specification --region us-east-1 --instance-credit-specification "InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

The following is example output:

```
{  
  "SuccessfulInstanceCreditSpecifications": [  
    {  
      "InstanceId": "i- 1234567890abcdef0"  
    }  
  ],  
  "UnsuccessfulInstanceCreditSpecifications": []  
}
```

Set the default credit specification for the account

You can set the default credit specification for each burstable performance instance family at the account level per AWS Region.

If you use the Launch Instance Wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new burstable performance instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

Consideration

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

To set the default credit specification at the account level (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the left navigation pane, choose **EC2 Dashboard**.

3. From **Account attributes**, choose **Default credit specification**.
4. Choose **Manage**.
5. For each instance family, choose **Unlimited** or **Standard**, and then choose **Update**.

To set the default credit specification at the account level (AWS CLI)

Use the [modify-default-credit-specification](#) command. Specify the AWS Region, instance family, and the default credit specification using the --cpu-credits parameter. Valid default credit specifications are **unlimited** and **standard**.

```
aws ec2 modify-default-credit-specification --region us-east-1 --instance-family t2 --cpu-credits unlimited
```

View the default credit specification

You can view the default credit specification of a burstable performance instance family at the account level per AWS Region.

To view the default credit specification at the account level (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **Default credit specification**.

To view the default credit specification at the account level (AWS CLI)

Use the [get-default-credit-specification](#) command. Specify the AWS Region and instance family.

```
aws ec2 get-default-credit-specification --region us-east-1 --instance-family t2
```

Monitor your CPU credits

You can see the credit balance for each instance in the Amazon EC2 per-instance metrics of the CloudWatch console.

- [Additional CloudWatch metrics for burstable performance instances \(p. 296\)](#)
- [Calculate CPU credit usage \(p. 298\)](#)

[Additional CloudWatch metrics for burstable performance instances](#)

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

- **CPUCreditUsage** – The number of CPU credits spent during the measurement period.
- **CPUCreditBalance** – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
- **CPUSurplusCreditBalance** – The number of surplus CPU credits spent to sustain CPU utilization when the CPUCreditBalance value is zero.
- **CPUSurplusCreditsCharged** – The number of surplus CPU credits exceeding the [maximum number of CPU credits \(p. 271\)](#) that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as `unlimited`.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see [List the available CloudWatch metrics for your instances \(p. 978\)](#).

Metric	Description
<code>CPUCreditUsage</code>	<p>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</p> <p>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the <code>Sum</code> statistic instead of the <code>Average</code> statistic.</p> <p>Units: Credits (vCPU-minutes)</p>
<code>CPUCreditBalance</code>	<p>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the <code>CPUCreditBalance</code> also includes the number of launch credits that have been accrued.</p> <p>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.</p> <p>The credits in the <code>CPUCreditBalance</code> are available for the instance to spend to burst beyond its baseline CPU utilization.</p> <p>When an instance is running, credits in the <code>CPUCreditBalance</code> do not expire. When a T4g, T3a or T3 instance stops, the <code>CPUCreditBalance</code> value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the <code>CPUCreditBalance</code> value does not persist, and all accrued credits are lost.</p> <p>CPU credit metrics are available at a five-minute frequency only.</p> <p>Units: Credits (vCPU-minutes)</p>
<code>CPUSurplusCreditBalance</code>	<p>The number of surplus credits that have been spent by an unlimited instance when its <code>CPUCreditBalance</code> value is zero.</p> <p>The <code>CPUSurplusCreditBalance</code> value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge.</p> <p>Units: Credits (vCPU-minutes)</p>
<code>CPUSurplusCreditsCharged</code>	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.

Metric	Description
	<p>Spent surplus credits are charged when any of the following occurs:</p> <ul style="list-style-type: none"> The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. The instance is stopped or terminated. The instance is switched from <code>unlimited</code> to <code>standard</code>. <p>Units: Credits (vCPU-minutes)</p>

Calculate CPU credit usage

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the *prior* value of a metric at any point in time implies the previous value of the metric, sent *five minutes ago*.

Calculate CPU credit usage for Standard instances

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

Example

```
CPUCreditBalance = prior CPUCreditBalance + [Credits earned per hour * (5/60) - CPUCreditUsage]
```

The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the [credit table \(p. 271\)](#).

Example

This example uses a `t3.nano` instance. To calculate the `CPUCreditBalance` value of the instance, use the preceding equation as follows:

- `CPUCreditBalance` – The current credit balance to calculate.
- `prior CPUCreditBalance` – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- `Credits earned per hour` – A `t3.nano` instance earns six credits per hour.
- `5/60` – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by `5/60` (five minutes) to get the number of credits that the instance earned in the past five minutes. A `t3.nano` instance earns 0.5 credits every five minutes.
- `CPUCreditUsage` – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the `CPUCreditBalance` value:

Example

```
CPUCreditBalance = 2 + [0.5 - 1] = 1.5
```

Calculate CPU credit usage for Unlimited instances

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term `Adjusted balance` in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the `CPUCreditBalance` and `CPUSurplusCreditBalance` CloudWatch metrics.

Example

```
Adjusted balance = [prior CPUCreditBalance - prior CPUSurplusCreditBalance] + [Credits earned per hour * (5/60) - CPUCreditUsage]
```

A value of 0 for `Adjusted balance` indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both `CPUCreditBalance` and `CPUSurplusCreditBalance` are set to 0.

A positive `Adjusted balance` value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the `Adjusted balance` value is assigned to `CPUCreditBalance`, and the `CPUSurplusCreditBalance` is set to 0. The instance size determines the [maximum number of credits \(p. 271\)](#) that it can accrue.

Example

```
CPUCreditBalance = min [max earned credit balance, Adjusted balance]  
CPUSurplusCreditBalance = 0
```

A negative `Adjusted balance` value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the `Adjusted balance` value is assigned to `CPUSurplusCreditBalance` and `CPUCreditBalance` is set to 0. Again, the instance size determines the [maximum number of credits \(p. 271\)](#) that it can accrue.

Example

```
CPUSurplusCreditBalance = min [max earned credit balance, -Adjusted balance]  
CPUCreditBalance = 0
```

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the `CPUSurplusCreditsCharged` metric.

Example

```
CPUSurplusCreditsCharged = max [-Adjusted balance - max earned credit balance, 0]
```

Finally, when the instance terminates, any surplus credits tracked by the `CPUSurplusCreditBalance` are charged. If the instance is switched from `unlimited` to `standard`, any remaining `CPUSurplusCreditBalance` is also charged.

Amazon EC2 Mac instances

Mac1 instances natively support the macOS operating system. They are built on Mac mini hardware and powered by 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processors. These instances are ideal for developing, building, testing, and signing applications for Apple devices, such as iPhone, iPad, iPod, Mac, Apple Watch, and Apple TV. You can connect to your Mac instance using SSH or Apple Remote Desktop (ARD).

Note

The **unit of billing** is the **dedicated host**. The instances running on top of that host have no additional charge.

For more information, see [Amazon EC2 Mac Instances and Pricing](#).

- [Stop and terminate your Mac instance \(p. 306\)](#)
- [Subscribe to macOS AMI notifications \(p. 307\)](#)
- [Release the Dedicated Host for your Mac instance \(p. 308\)](#)

Considerations

The following considerations apply to Mac instances:

- Mac instances are available only as bare metal instances on [Dedicated Hosts \(p. 498\)](#), with a minimum allocation period of 24 hours before you can release the Dedicated Host. You can launch one Mac instance per Dedicated Host. You can share the Dedicated Host with the AWS accounts or organizational units within your AWS organization, or the entire AWS organization.
- Mac instances are available only as On-Demand Instances. They are not available as Spot Instances or Reserved Instances. You can save money on Mac instances by purchasing a [Savings Plan](#).
- Mac instances can run one of the following operating systems:
 - macOS Catalina (version 10.15)
 - macOS Mojave (version 10.14)
 - macOS Big Sur (version 11)
 - macOS Monterey (version 12)
- If you attach an EBS volume to a running Mac instance, you must reboot the instance to make the volume available.
- If you resized an existing EBS volume on a running Mac instance, you must reboot the instance to make the new size available.

- If you attach a network interface to a running Mac instance, you must reboot the instance to make the network interface available.
- AWS does not manage or support the internal SSD on the Apple hardware. We strongly recommend that you use Amazon EBS volumes instead. EBS volumes provide the same elasticity, availability, and durability benefits on Mac instances as they do on any other EC2 instance.
- We recommend using General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2) with Mac instances for optimal EBS performance.
- You cannot use Mac instances with Amazon EC2 Auto Scaling.
- Automatic software updates are disabled. We recommend that you apply updates and test them on your instance before you put the instance into production. For more information, see [Update the operating system and software \(p. 304\)](#).
- When you stop or terminate a Mac instance, a scrubbing workflow is performed on the Dedicated Host. For more information, see [Stop and terminate your Mac instance \(p. 306\)](#).
 - **Warning**
Do not use FileVault. If data-at-rest and data-in-transit is required, use [EBS encryption](#) to avoid boot issues and performance impact. Enabling FileVault will result in the host failing to boot due to the partitions being locked.

Launch a Mac instance using the console

You can launch a Mac instance using the AWS Management Console as described in the following procedure. Mac instances require a [Dedicated Host \(p. 498\)](#).

To launch a Mac instance onto a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose **Allocate Dedicated Host** and then do the following:
 - a. For **Instance family**, choose **mac1**. If **mac1** doesn't appear in the list, it's not supported in the currently selected Region.
 - b. For **Instance type**, select **mac1.metal**.
 - c. For **Availability Zone**, choose the Availability Zone for the Dedicated Host.
 - d. For **Quantity**, keep **1**.
 - e. Choose **Allocate**.
4. Select the Dedicated Host that you created and then do the following:
 - a. Choose **Actions, Launch instances onto host**.
 - b. Select a macOS AMI.
 - c. Select the **mac1.metal** instance type.
 - d. On the **Configure Instance Details page**, verify that **Tenancy** and **Host** are preconfigured based on the Dedicated Host you created. Update **Affinity** as needed.
 - e. Complete the wizard, specifying EBS volumes, security groups, and key pairs as needed.
5. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console. The initial state of an instance is **pending**. The instance is ready when its state changes to **running** and it passes status checks.

Launch a Mac instance using the AWS CLI

Use the following [allocate-hosts](#) command to allocate a Dedicated Host for your Mac instance.

```
aws ec2 allocate-hosts --region us-east-1 --instance-type mac1.metal --availability-zone us-east-1b --auto-placement "on" --quantity 1
```

Use the following [run-instances](#) command to launch a Mac instance.

```
aws ec2 run-instances --region us-east-1 --instance-type mac1.metal --placement Tenancy=host --image-id ami_id --key-name my-key-pair
```

The initial state of an instance is pending. The instance is ready when its state changes to running and it passes status checks. Use the following [describe-instance-status](#) command to display status information for your instance:

```
aws ec2 describe-instance-status --instance-ids i-017f8354e2dc69c4f
```

The following is example output for an instance that is running and has passed status checks.

```
{
    "InstanceStatuses": [
        {
            "AvailabilityZone": "us-east-1b",
            "InstanceId": "i-017f8354e2dc69c4f",
            "InstanceState": {
                "Code": 16,
                "Name": "running"
            },
            "InstanceStatus": {
                "Details": [
                    {
                        "Name": "reachability",
                        "Status": "passed"
                    }
                ],
                "Status": "ok"
            },
            "SystemStatus": {
                "Details": [
                    {
                        "Name": "reachability",
                        "Status": "passed"
                    }
                ],
                "Status": "ok"
            }
        }
    ]
}
```

Connect to your instance using SSH

Amazon EC2 Mac instances do not allow remote root SSH by default. Password authentication is disabled to prevent brute-force password attacks. The ec2-user account is configured to log in remotely using SSH. The ec2-user account also has **sudo** privileges. After you connect to your instance, you can add other users.

To support connecting to your instance using SSH, launch the instance using a key pair and a security group that allows SSH access, and ensure that the instance has internet connectivity. You provide the `.pem` file for the key pair when you connect to the instance.

Use the following procedure to connect to your Mac instance using an SSH client. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

To connect to your instance using SSH

1. Verify that your local computer has an SSH client installed by entering **ssh** at the command line. If your computer doesn't recognize the command, search for an SSH client for your operating system and install it.
2. Get the public DNS name of your instance. Using the Amazon EC2 console, you can find the public DNS name on both the **Details** and the **Networking** tabs. Using the AWS CLI, you can find the public DNS name using the `describe-instances` command.
3. Locate the `.pem` file for the key pair that you specified when you launched the instance.
4. Connect to your instance using the following **ssh** command, specifying the public DNS name of the instance and the `.pem` file.

```
ssh -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name
```

Connect to your instance using Apple Remote Desktop

Use the following procedure to connect to your instance using Apple Remote Desktop (ARD).

Note

macOS 10.14 and later only allows control if Screen Sharing is enabled through [System Preferences](#).

To connect to your instance using ARD

1. Verify that your local computer has an ARD client or a VNC client that supports ARD installed. On macOS, you can leverage the built-in Screen Sharing application. Otherwise, search for ARD for your operating system and install it.
2. From your local computer, [connect to your instance using SSH \(p. 302\)](#).
3. Set up a password for the `ec2-user` account using the **passwd** command as follows.

```
[ec2-user ~]$ sudo passwd ec2-user
```

4. Start the Apple Remote Desktop agent and enable remote desktop access as follows.

```
[ec2-user ~]$ sudo /System/Library/CoreServices/RemoteManagement/ARDAgent.app/Contents/Resources/kickstart \
-activate -configure -access -on \
-restart -agent -privs -all
```

5. From your computer, connect to your instance using the following **ssh** command. In addition to the options shown in the previous section, use the **-L** option to enable port forwarding and forward all traffic on local port 5900 to the ARD server on the instance.

```
ssh -L 5900:localhost:5900 -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name
```

6. From your local computer, use the ARD client or VNC client that supports ARD to connect to localhost on port 5900. For example, use the Screen Sharing application on macOS as follows:
 - a. Open Finder and launch the Screen Sharing application.
 - b. For **Connect to**, enter **localhost**.
 - c. Log in as prompted, using `ec2-user` as the user name and the password that you created for the `ec2-user` account.

Modify macOS screen resolution on Mac instances

Once you connect to your EC2 Mac instance using ARD or a VNC client that supports ARD installed, you can modify the screen resolution of your macOS environment using any of the publicly available macOS tools or utilities, such as [displayplacer](#)

Modifying screen resolution using displayplacer

1. Install displayplacer.

```
brew tap jakehilborn/jakehilborn && brew install displayplacer
```

2. Show current screen info and possible screen resolutions.

```
displayplacer list
```

3. Apply desired screen resolution.

```
displayplacer "id:<screenID> res:<width>x<height> origin:(0,0) degree:0"
```

For example:

```
RES="2560x1600"
displayplacer "id:69784AF1-CD7D-B79B-E5D4-60D937407F68 res:${RES} scaling:off origin:(0,0) degree:0"
```

EC2 macOS AMIs

Amazon EC2 macOS is designed to provide a stable, secure, and high-performance environment for developer workloads running on Amazon EC2 Mac instances. EC2 macOS AMIs includes packages that enable easy integration with AWS, such as launch configuration tools and popular AWS libraries and tools. EC2 macOS AMIs include the following by default:

- ENA drivers
- EC2 macOS Init
- EC2 System Monitoring for macOS
- SSM Agent for macOS
- AWS Command Line Interface (AWS CLI) version 2
- Command Line Tools for Xcode
- Homebrew

AWS provides updated EC2 macOS AMIs on a regular basis that include updates to AWS-owned packages and the latest fully-tested macOS version. Additionally, AWS provides updated AMIs with the latest minor version updates or major version updates as soon as they can be fully tested and vetted. If you do not need to preserve data or customizations to your Mac instances, you can get the latest updates by launching a new instance using the current AMI and then terminating the previous instance. Otherwise, you can choose which updates to apply to your Mac instances.

Update the operating system and software

You can install operating system updates from Apple using the **softwareupdate** command.

To install operating system updates from Apple

1. List the packages with available updates using the following command.

```
[ec2-user ~]$ softwareupdate --list
```

2. Install all updates or only specific updates. To install specific updates, use the following command.

```
[ec2-user ~]$ sudo softwareupdate --install label
```

To install all updates instead, use the following command.

```
[ec2-user ~]$ sudo softwareupdate --install --all
```

System administrators can use AWS Systems Manager to roll out pre-approved operating system updates. For more information, see the [AWS Systems Manager User Guide](#).

You can use Homebrew to install updates to packages in the EC2 macOS AMIs, so that you have the latest version of these packages on your instances. You can also use Homebrew to install and run common macOS applications on Amazon EC2 macOS. For more information, see the [Homebrew Documentation](#).

To install updates using Homebrew

1. Update Homebrew using the following command.

```
[ec2-user ~]$ brew update
```

2. List the packages with available updates using the following command.

```
[ec2-user ~]$ brew outdated
```

3. Install all updates or only specific updates. To install specific updates, use the following command.

```
[ec2-user ~]$ brew upgrade formula
```

To install all updates instead, use the following command.

```
[ec2-user ~]$ brew upgrade
```

Warning

Do not install beta or prerelease macOS versions on your EC2 Mac instances, as this configuration is currently not supported. Installing beta or prerelease macOS versions will lead to degradation of your EC2 Mac Dedicated Host when you stop or terminate your instance, and will prevent you from starting or launching a new instance on that host.

EC2 macOS Init

EC2 macOS Init is used to initialize EC2 Mac instances at launch. It uses priority groups to run logical groups of tasks at the same time.

The launchd plist file is `/Library/LaunchDaemons/com.amazon.ec2.macos-init.plist`. The files for EC2 macOS Init are located in `/usr/local/aws/ec2-macos-init`.

For more information, see <https://github.com/aws/ec2-macos-init>.

EC2 System Monitoring for macOS

EC2 System Monitoring for macOS provides CPU utilization metrics to Amazon CloudWatch. It sends these metrics to CloudWatch over a custom serial device in 1-minute periods. You can enable or disable this agent as follows. It is enabled by default.

```
sudo setup-ec2monitoring [enable | disable]
```

Increase the size of an EBS volume on your Mac instance

You can increase the size of your Amazon EBS volumes on your Mac instance. For more information, see [Amazon EBS Elastic Volumes \(p. 1529\)](#).

After you increase the size of the volume, you must increase the size of your APFS container as follows.

Make increased disk space available for use

1. Determine if a restart is needed. If you resized an existing EBS volume on a running Mac instance, you must **reboot** the instance to make the new size available. If disk space modification was done during launch time, a reboot will not be needed.

View current status of disk sizes:

```
[ec2-user ~]$ diskutil list external physical
/dev/disk0 (external, physical):
#:          TYPE NAME                SIZE      IDENTIFIER
0: GUID_partition_scheme            *322.1 GB   disk0
1: EFI     EFI                  209.7 MB   disk0s1
2: Apple_APFS Container disk2      321.9 GB   disk0s2
```

2. Copy and paste the following command.

```
PDISK=$(diskutil list physical external | head -n1 | cut -d" " -f1)
APFSCONT=$(diskutil list physical external | grep "Apple_APFS" | tr -s " " | cut -d" " -f8)
yes | sudo diskutil repairDisk $PDISK
```

3. Copy and paste the following command.

```
sudo diskutil apfs resizeContainer $APFSCONT 0
```

Stop and terminate your Mac instance

When you stop a Mac instance, the instance remains in the stopping state for about 15 minutes before it enters the stopped state.

When you stop or terminate a Mac instance, Amazon EC2 performs a scrubbing workflow on the underlying Dedicated Host to erase the internal SSD, to clear the persistent NVRAM variables, and if needed, to update the bridgeOS software on the underlying Mac mini. This ensures that Mac instances provide the same security and data privacy as other EC2 Nitro instances. It also enables you to run the latest macOS AMIs without manually updating the bridgeOS software. During the scrubbing workflow, the Dedicated Host temporarily enters the pending state. If the bridgeOS software does not need to be updated, the scrubbing workflow takes up to 50 minutes to complete. If the bridgeOS software needs to be updated, the scrubbing workflow can take up to 3 hours to complete.

You can't start the stopped Mac instance or launch a new Mac instance until after the scrubbing workflow completes, at which point the Dedicated Host enters the available state.

Metering and billing is paused when the Dedicated Host enters the pending state. You are not charged for the duration of the scrubbing workflow.

Subscribe to macOS AMI notifications

To be notified when new AMIs are released or when bridgeOS has been updated, subscribe for notifications using Amazon SNS.

To subscribe to macOS AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. For the **Create subscription** dialog box, do the following:
 - a. For **Topic ARN**, copy and paste one of the following Amazon Resource Names (ARNs):
 - `arn:aws:sns:us-east-1:898855652048:amazon-ec2-macos-ami-updates`
 - `arn:aws:sns:us-east-1:898855652048:amazon-ec2-bridgeos-updates`

For Protocol:

- b. **Email:**

For **Endpoint**, type an email address that you can use to receive the notifications. After you create your subscription you'll receive a confirmation message with the subject line AWS Notification – Subscription Confirmation. Open the email and choose **Confirm subscription** to complete your subscription

- c. **SMS:**

For **Endpoint**, type a phone number that you can use to receive the notifications.

- d. **AWS Lambda, Amazon SQS, Amazon Kinesis Data Firehose** (*Notifications come in JSON format*):

For **Endpoint**, enter the ARN for the Lambda function, SQS queue, or Firehose stream you can use to receive the notifications.

- e. Choose **Create subscription**.

Whenever macOS AMIs are released, we send notifications to the subscribers of the `amazon-ec2-macos-ami-updates` topic. Whenever bridgeOS is updated, we send notifications to the subscribers of the `amazon-ec2-bridgeos-updates` topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from macOS AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications were created in this Region.
3. In the navigation pane, choose **Subscriptions**.

4. Select the subscriptions and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Release the Dedicated Host for your Mac instance

When you are finished with your Mac instance, you can release the Dedicated Host. Before you can release the Dedicated Host, you must stop or terminate the Mac instance. You cannot release the host until the allocation period exceeds the 24-hour minimum.

To release the Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, then choose either **Stop instance** or **Terminate instance**.
4. In the navigation pane, choose **Dedicated Hosts**.
5. Select the Dedicated Host and choose **Actions, Release host**.
6. When prompted for confirmation, choose **Release**.

Compute optimized instances

Compute optimized instances are ideal for compute-bound applications that benefit from high-performance processors.

C5 and C5n instances

These instances are well suited for the following:

- Batch processing workloads
- Media transcoding
- High-performance web servers
- High-performance computing (HPC)
- Scientific modeling
- Dedicated gaming servers and ad serving engines
- Machine learning inference and other compute-intensive applications

Bare metal instances, such as `c5.meta1`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 C5 Instances](#).

C6g, C6gd, and C6gn instances

These instances are powered by AWS Graviton2 processors and are ideal for running advanced, compute-intensive workloads, such as the following:

- High-performance computing (HPC)
- Batch processing
- Ad serving
- Video encoding

- Gaming servers
- Scientific modeling
- Distributed analytics
- CPU-based machine learning inference

Bare metal instances, such as `c6g.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 C6g Instances](#).

C6i instances

These instances are ideal for running advanced, compute-intensive workloads, such as the following:

- High-performance computing (HPC)
- Batch processing
- Ad serving
- Video encoding
- Distributed analytics
- Highly scalable multiplayer gaming

For more information, see [Amazon EC2 C6i Instances](#).

Hpc6a instances

These instances are ideal for running high performance computing (HPC) workloads, such as the following:

- Molecular dynamics
- Computational chemistry
- Computational fluid dynamics
- Weather forecasting
- Materials simulation
- Crash simulations
- Astrophysics

For more information, see [Amazon EC2 Hpc6a Instances](#).

For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

For more information about specifying CPU options, see [Optimize CPU options \(p. 691\)](#).

Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some compute optimized instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

Some compute optimized instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see [Processor state control for your EC2 instance \(p. 678\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).

The following is a summary of network performance for compute optimized instances that support enhanced networking.

c6gd.metal	860,000	360,000

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 1635\)](#).

Instance features

The following is a summary of features for compute optimized instances:

Release notes

- C5 and C5d instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- C5a and C5ad instances feature a second-generation AMD EPYC processor (Rome) running at frequencies as high as 3.3. GHz.
- C6g, C6gd, and C6gn instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- C4 instances and instances built on the [Nitro System \(p. 247\)](#) require 64-bit EBS-backed HVM AMIs. They have high-memory and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the Nitro System have the following requirements:
 - [NVMe drivers \(p. 1558\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1125\)](#) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Instances with an AWS Graviton processors have the following requirements:
 - Use an AMI for the 64-bit Arm architecture.
 - Support booting through UEFI with ACPI tables and support ACPI hot-plug of PCI devices.

The following AMIs meet these requirements:

- Amazon Linux 2 (64-bit Arm)
- Ubuntu 16.04 or later (64-bit Arm)
- Red Hat Enterprise Linux 8.0 or later (64-bit Arm)
- SUSE Linux Enterprise Server 15 or later (64-bit Arm)
- Debian 10 or later (64-bit Arm)
- To get the best performance from your C6i instances, ensure that they have ENA driver version 2.2.9 or later. Using an ENA driver earlier than version 1.2 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - Amazon Linux 2 with kernel 4.14.186
 - Ubuntu 20.04 with kernel 5.4.0-1025-aws
 - Red Hat Enterprise Linux 8.3 with kernel 4.18.0-240.1.1.el8_3.ARCH
 - SUSE Linux Enterprise Server 15 SP2 with kernel 5.3.18-24.15.1
- Instances built on the Nitro System instances support a maximum of 28 attachments, including network interfaces, EBS volumes, and NVMe instance store volumes. For more information, see [Nitro System volume limits \(p. 1644\)](#).
- To get the best performance from your C6gn instances, ensure that they have ENA driver version 2.2.9 or later. Using an ENA driver earlier than version 1.2 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.

- Amazon Linux 2 with kernel 4.14.186
- Ubuntu 20.04 with kernel 5.4.0-1025-aws
- Red Hat Enterprise Linux 8.3 with kernel 4.18.0-240.1.1.el8_3.ARCH
- SUSE Linux Enterprise Server 15 SP2 with kernel 5.3.18-24.15.1
- **Traffic Mirroring** is not supported on C6gn instances.
- To launch AMIs for all Linux distributions on C6gn instances, use AMIs with the latest version and run an update for the latest driver. For earlier versions, download the latest driver from [GitHub](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- Instances built on the Nitro System should have acpid installed to support clean shutdown through API requests.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Memory optimized instances

Memory optimized instances are designed to deliver fast performance for workloads that process large data sets in memory.

R5, R5a, R5b, and R5n instances

These instances are well suited for the following:

- High-performance, relational (MySQL) and NoSQL (MongoDB, Cassandra) databases.
- Distributed web scale cache stores that provide in-memory caching of key-value type data (Memcached and Redis).
- In-memory databases using optimized data storage formats and analytics for business intelligence (for example, SAP HANA).
- Applications performing real-time processing of big unstructured data (financial services, Hadoop/Spark clusters).
- High-performance computing (HPC) and Electronic Design Automation (EDA) applications.

R5b instances support io2 Block Express volumes. All io2 volumes attached to an R5b instance during or after launch automatically run on EBS Block Express. For more information, see [io2 Block Express volumes](#).

Bare metal instances, such as r5.meta1, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 R5 Instances](#).

R6g and R6gd instances

These instances are powered by AWS Graviton2 processors and are ideal for running memory-intensive workloads, such as the following:

- Open-source databases (for example, MySQL, MariaDB, and PostgreSQL)
- In-memory caches (for example, Memcached, Redis, and KeyDB)

Bare metal instances, such as `r6g.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 R6g Instances](#).

R6i instances

These instances are ideal for running memory-intensive workloads, such as the following:

- High-performance databases (relational and NoSQL)
- In-memory databases, such as SAP HANA
- Distributed web scale in-memory caches, such as Memcached and Redis
- Real-time big data analytics, such as Hadoop and Spark clusters

For more information, see [Amazon EC2 R6i Instances](#).

High memory (u-*) instances

These instances offer 3 TiB, 6 TiB, 9 TiB, 12 TiB, 18 TiB, and 24 TiB of memory per instance. They are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database.

For more information, see [Amazon EC2 High Memory Instances](#) and [Storage Configuration for SAP HANA](#). For information about supported operating systems, see [Migrating SAP HANA on AWS to an EC2 High Memory Instance](#).

X1 instances

These instances are well suited for the following:

- In-memory databases such as SAP HANA, including SAP-certified support for Business Suite S/4HANA, Business Suite on HANA (SoH), Business Warehouse on HANA (BW), and Data Mart Solutions on HANA. For more information, see [SAP HANA on the AWS Cloud](#).
- Big-data processing engines such as Apache Spark or Presto.
- High-performance computing (HPC) applications.

For more information, see [Amazon EC2 X1 Instances](#).

X1e instances

These instances are well suited for the following:

- High-performance databases.
- In-memory databases such as SAP HANA. For more information, see [SAP HANA on the AWS Cloud](#).

- Memory-intensive enterprise applications.

For more information, see [Amazon EC2 X1e Instances](#).

X2gd instances

These instances are well suited for the following:

- In-memory databases, such as Redis and Memcached.
- Relational databases, such as MySQL and PostGreSQL.
- Electronic design automation (EDA) workloads, such as physical verification and layout tools.
- Memory-intensive workloads, such as real-time analytics and real-time caching servers.

For more information, see [Amazon EC2 X2g Instances](#).

X2iezn instances

These instances are well suited for the following:

- In-memory databases, such as Redis and Memcached.
- Relational databases, such as MySQL and PostGreSQL.
- Electronic design automation (EDA) workloads, such as physical verification and layout tools.
- Memory-intensive workloads, such as real-time analytics and real-time caching servers.

For more information, see [Amazon EC2 X2i Instances](#).

z1d instances

These instances deliver both high compute and high memory and are well-suited for the following:

- Electronic Design Automation (EDA)
- Relational database workloads

`z1d.metal` instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 z1d Instances](#).

For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

For more information about specifying CPU options, see [Optimize CPU options \(p. 691\)](#).

Memory performance

X1 instances include Intel Scalable Memory Buffers, providing 300 GiB/s of sustainable memory-read bandwidth and 140 GiB/s of sustainable memory-write bandwidth.

For more information about how much RAM can be enabled for memory optimized instances, see [Hardware specifications \(p. 321\)](#).

Memory optimized instances have high memory and require 64-bit HVM AMIs to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on memory optimized instances. For more information, see [Linux AMI virtualization types \(p. 108\)](#).

Instance performance

Memory optimized instances enable increased cryptographic performance through the latest Intel AES-NI feature, support Intel Transactional Synchronization Extensions (TSX) to boost the performance of in-memory transactional data processing, and support Advanced Vector Extensions 2 (Intel AVX2) processor instructions to expand most integer commands to 256 bits.

Some memory optimized instances provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (measured by CPU frequency) from a core. For more information, see [Processor state control for your EC2 instance \(p. 678\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 1635\)](#).

Support for vCPUs

Memory optimized instances provide a high number of vCPUs, which can cause launch issues with operating systems that have a lower vCPU limit. We strongly recommend that you use the latest AMIs when you launch memory optimized instances.

The following AMIs support launching memory optimized instances:

- [Amazon Linux 2 \(HVM\)](#)

Release notes

- R4 instances feature up to 64 vCPUs and are powered by two AWS-customized Intel XEON processors based on E5-2686v4 that feature high-memory bandwidth and larger L3 caches to boost the performance of in-memory applications.
- R5, R5b, and R5d instances feature a 3.1 GHz Intel Xeon Platinum 8000 series processor from either the first generation (Skylake-SP) or second generation (Cascade Lake).
- R5a and R5ad instances feature a 2.5 GHz AMD EPYC 7000 series processor.
- R6g and R6gd instances feature an AWS Graviton2 processor based on 64-bit Arm architecture.
- High memory instances (`u-6tb1.metal`, `u-9tb1.metal`, and `u-12tb1.metal`) are the first instances to be powered by an eight-socket platform with the latest generation Intel Xeon Platinum 8176M (Skylake) processors that are optimized for mission-critical enterprise workloads. High Memory instances with 18 TB and 24 TB of memory (`u-18tb1.metal` and `u-24tb1.metal`) are the first instances powered by an 8-socket platform with 2nd Generation Intel Xeon Scalable 8280L (Cascade Lake) processors.
- X1e and X1 instances feature up to 128 vCPUs and are powered by four Intel Xeon E7-8880 v3 processors that feature high-memory bandwidth and larger L3 caches to boost the performance of in-memory applications.
- X2iezn instances feature a custom Intel Xeon Scalable processor (Cascade Lake).
- Instances built on the Nitro System have the following requirements:
 - [NVMe drivers \(p. 1558\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1125\)](#) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Instances with an AWS Graviton processors have the following requirements:
 - Use an AMI for the 64-bit Arm architecture.
 - Support booting through UEFI with ACPI tables and support ACPI hot-plug of PCI devices.

The following AMIs meet these requirements:

- Amazon Linux 2 (64-bit Arm)
- Ubuntu 16.04 or later (64-bit Arm)
- Red Hat Enterprise Linux 8.0 or later (64-bit Arm)
- SUSE Linux Enterprise Server 15 or later (64-bit Arm)
- Debian 10 or later (64-bit Arm)
- To get the best performance from your R6i instances, ensure that they have ENA driver version 2.2.9 or later. Using an ENA driver earlier than version 1.2 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - Amazon Linux 2 with kernel 4.14.186
 - Ubuntu 20.04 with kernel 5.4.0-1025-aws
 - Red Hat Enterprise Linux 8.3 with kernel 4.18.0-240.1.1.el8_3.ARCH
 - SUSE Linux Enterprise Server 15 SP2 with kernel 5.3.18-24.15.1

- Instances built on the Nitro System instances support a maximum of 28 attachments, including network interfaces, EBS volumes, and NVMe instance store volumes. For more information, see [Nitro System volume limits \(p. 1644\)](#).
- All `io2` volumes attached to an R5b instance during or after launch automatically run on EBS Block Express. For more information, see [io2 Block Express volumes](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y  
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- You can't launch X1 instances using a Windows Server 2008 SP2 64-bit AMI, except for `x1.16xlarge` instances.
- You can't launch X1e instances using a Windows Server 2008 SP2 64-bit AMI.
- With earlier versions of the Windows Server 2008 R2 64-bit AMI, you can't launch `r4.1.large` and `r4.4xlarge` instances. If you experience this issue, update to the latest version of this AMI.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Storage optimized instances

Storage optimized instances are designed for workloads that require high, sequential read and write access to very large data sets on local storage. They are optimized to deliver tens of thousands of low-latency, random I/O operations per second (IOPS) to applications.

D2 instances

These instances are well suited for the following:

- Massive parallel processing (MPP) data warehouse
- MapReduce and Hadoop distributed computing
- Log or data processing applications

D3 and D3en instances

These instances offer scale out of instance storage and are well suited for the following:

- Distributed file systems for Hadoop workloads
- File storage workloads such as GPFS and BeeFS
- Large data lakes for HPC workloads

H1 instances

These instances are well suited for the following:

- Data-intensive workloads such as MapReduce and distributed file systems
- Applications requiring sequential access to large amounts of data on direct-attached instance storage
- Applications that require high-throughput access to large quantities of data

I3 and I3en instances

These instances are well suited for the following:

- High frequency online transaction processing (OLTP) systems
- Relational databases
- NoSQL databases
- Cache for in-memory databases (for example, Redis)
- Data warehousing applications
- Distributed file systems

Bare metal instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 I3 Instances](#).

Im4gn instances

These instances are well suited for workloads that require high random I/O performance at a low latency, such as the following:

- Relational databases
- NoSQL databases
- Search
- Distributed file systems

For more information, see [Amazon EC2 Im4gn and Is4gen Instances](#).

Is4gen instances

These instances are well suited for workloads that require high random I/O performance at a low latency, such as the following:

- NoSQL databases
- Indexing
- Streaming
- Caching
- Warm storage

For more information, see [Amazon EC2 Im4gn and Is4gen Instances](#).

Hardware specifications

The primary data storage for D2, D3, and D3en instances is HDD instance store volumes. The primary data storage for I3 and I3en instances is non-volatile memory express (NVMe) SSD instance store volumes.

Instance store volumes persist only for the life of the instance. When you stop, hibernate, or terminate an instance, the applications and data in its instance store volumes are erased. We recommend that you regularly back up or replicate important data in your instance store volumes. For more information, see [Amazon EC2 instance store \(p. 1620\)](#) and [SSD instance store volumes \(p. 1634\)](#).

For more information about specifying CPU options, see [Optimize CPU options \(p. 691\)](#).

Instance performance

To ensure the best disk throughput performance from your instance on Linux, we recommend that you use the most recent version of Amazon Linux 2 or the Amazon Linux AMI.

For instances with NVMe instance store volumes, you must use a Linux AMI with kernel version 4.4 or later. Otherwise, your instance will not achieve the maximum IOPS performance available.

D2 instances provide the best disk performance when you use a Linux kernel that supports persistent grants, an extension to the Xen block ring protocol that significantly improves disk throughput and scalability. For more information about persistent grants, see [this article](#) in the Xen Project Blog.

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some storage optimized instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

Some storage optimized instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see [Processor state control for your EC2 instance \(p. 678\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).

The following is a summary of network performance for storage optimized instances that support enhanced networking.

Support for vCPUs

The `d2.8xlarge` instance type provides 36 vCPUs, which might cause launch issues in some Linux operating systems that have a vCPU limit of 32. We strongly recommend that you use the latest AMIs when you launch `d2.8xlarge` instances.

The following Linux AMIs support launching `d2.8xlarge` instances with 36 vCPUs:

- Amazon Linux 2 (HVM)
- Amazon Linux AMI 2018.03 (HVM)
- Ubuntu Server 14.04 LTS (HVM) or later
- Red Hat Enterprise Linux 7.1 (HVM)
- SUSE Linux Enterprise Server 12 (HVM)

If you must use a different AMI for your application, and your `d2.8xlarge` instance launch does not complete successfully (for example, if your instance status changes to `stopped` during launch with a `Client.InstanceInitiatedShutdown` state transition reason), modify your instance as described in the following procedure to support more than 32 vCPUs so that you can use the `d2.8xlarge` instance type.

To update an instance to support more than 32 vCPUs

1. Launch a D2 instance using your AMI, choosing any D2 instance type other than `d2.8xlarge`.
2. Update the kernel to the latest version by following your operating system-specific instructions. For example, for RHEL 6, use the following command:

```
sudo yum update -y kernel
```

3. Stop the instance.
4. (Optional) Create an AMI from the instance that you can use to launch any additional `d2.8xlarge` instances that you need in the future.
5. Change the instance type of your stopped instance to `d2.8xlarge` (choose **Actions**, **Instance settings**, **Change instance type**, and then follow the directions).
6. Start the instance. If the instance launches properly, you are done. If the instance still does not boot properly, proceed to the next step.
7. (Optional) If the instance still does not boot properly, the kernel on your instance may not support more than 32 vCPUs. However, you may be able to boot the instance if you limit the vCPUs.
 - a. Change the instance type of your stopped instance to any D2 instance type other than `d2.8xlarge` (choose **Actions**, **Instance settings**, **Change instance type**, and then follow the directions).
 - b. Add the `maxcpus=32` option to your boot kernel parameters by following your operating system-specific instructions. For example, for RHEL 6, edit the `/boot/grub/menu.lst` file and add the following option to the most recent and active kernel entry:

```
default=0
timeout=1
splashimage=(hd0,0)/boot/grub/splash.xpm.gz
hiddenmenu

- c. Stop the instance.
- d. (Optional) Create an AMI from the instance that you can use to launch any additional d2.8xlarge instances that you need in the future.
- e. Change the instance type of your stopped instance to d2.8xlarge (choose **Actions, Instance Settings, Change Instance Type**, and then follow the directions).
- f. Start the instance.

Release notes

- Instances built on the [Nitro System \(p. 247\)](#) have the following requirements:
 - [NVMe drivers \(p. 1558\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1125\)](#) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with linux-aws kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Instances with an AWS Graviton processors have the following requirements:
 - Use an AMI for the 64-bit Arm architecture.
 - Support booting through UEFI with ACPI tables and support ACPI hot-plug of PCI devices.

The following AMIs meet these requirements:

- Amazon Linux 2 (64-bit Arm)
- Ubuntu 16.04 or later (64-bit Arm)
- Red Hat Enterprise Linux 8.0 or later (64-bit Arm)
- SUSE Linux Enterprise Server 15 or later (64-bit Arm)
- Debian 10 or later (64-bit Arm)
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y  
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
344

- With FreeBSD AMIs, bare metal instances take nearly an hour to boot and I/O to the local NVMe storage does not complete. As a workaround, add the following line to `/boot/loader.conf` and reboot:

```
hw.nvme.per_cpu_io_queues="0"
```

- The `d2.8xlarge` instance type has 36 vCPUs, which might cause launch issues in some Linux operating systems that have a vCPU limit of 32. For more information, see [Support for vCPUs \(p. 343\)](#).
- The `d3.8xlarge` and `d3en.12xlarge` instances support a maximum of three attachments, including the root volume. If you exceed the attachment limit when you add a network interface or EBS volume, this causes attachment issues on your instance.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Linux accelerated computing instances

Accelerated computing instances use hardware accelerators, or co-processors, to perform some functions, such as floating point number calculations, graphics processing, or data pattern matching, more efficiently than is possible in software running on CPUs. These instances enable more parallelism for higher throughput on compute-intensive workloads.

If you require high processing capability, you'll benefit from using accelerated computing instances, which provide access to hardware-based compute accelerators such as Graphics Processing Units (GPUs), Field Programmable Gate Arrays (FPGAs), or AWS Inferentia.

GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

G5 instances

G5 instances use NVIDIA A10G GPUs and provide high performance for graphics-intensive applications such as remote workstations, video rendering, and cloud gaming, and deep learning models for applications such as natural language processing, computer vision, and recommendation engines. These instances feature up to 8 NVIDIA A10G GPUs, second generation AMD EPY processors, up to 100 Gbps of network bandwidth, and up to 7.6 TB of local NVMe SSD storage.

For more information, see [Amazon EC2 G5 Instances](#).

G5g instances

G5g instances use NVIDIA T4G GPUs and provide high performance for graphics-intensive applications such as game streaming and rendering that leverage industry-standard APIs, such as OpenGL and Vulkan. These instances are also suitable for running deep learning models for applications such as natural language processing and computer vision. These instances feature up to 2 NVIDIA T4G Tensor Core GPUs, AWS Graviton2 processors, and up to 25 Gbps of network bandwidth.

For more information, see [Amazon EC2 G5g Instances](#).

G4ad and G4dn instances

G4ad instances use AMD Radeon Pro V520 GPUs and 2nd generation AMD EPYC processors, and are well-suited for graphics applications such as remote graphics workstations, game streaming, and rendering that leverage industry-standard APIs such as OpenGL, DirectX, and Vulkan. They provide up to 4 AMD Radeon Pro V520 GPUs, 64 vCPUs, 25 Gbps networking, and 2.4 TB local NVMe-based SSD storage.

G4dn instances use NVIDIA Tesla GPUs and provide a cost-effective, high-performance platform for general purpose GPU computing using the CUDA or machine learning frameworks along with graphics applications using DirectX or OpenGL. These instances provide high-bandwidth networking, powerful half and single-precision floating-point capabilities, along with INT8 and INT4 precisions. Each GPU has 16 GiB of GDDR6 memory, making G4dn instances well-suited for machine learning inference, video transcoding, and graphics applications like remote graphics workstations and game streaming in the cloud.

For more information, see [Amazon EC2 G4 Instances](#).

G4dn instances support NVIDIA GRID Virtual Workstation. For more information, see [NVIDIA Marketplace offerings](#).

G3 instances

These instances use NVIDIA Tesla M60 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. G3 instances also provide NVIDIA GRID Virtual Workstation features, such as support for four monitors with resolutions up to 4096x2160, and NVIDIA GRID Virtual Applications. G3 instances are well-suited for applications such as 3D visualizations, graphics-intensive remote workstations, 3D rendering, video encoding, virtual reality, and other server-side graphics workloads requiring massively parallel processing power.

For more information, see [Amazon EC2 G3 Instances](#).

G3 instances support NVIDIA GRID Virtual Workstation and NVIDIA GRID Virtual Applications. To activate either of these features, see [Activate NVIDIA GRID Virtual Applications \(p. 377\)](#).

G2 instances

These instances use NVIDIA GRID K520 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. NVIDIA GRID GPUs also support NVIDIA's fast capture and encode API operations. Example applications include video creation services, 3D visualizations, streaming graphics-intensive applications, and other server-side graphics workloads.

P4d instances

These instances use NVIDIA A100 GPUs and provide a high-performance platform for machine learning and HPC workloads. P4d instances offer 400 Gbps of aggregate network bandwidth throughput and support, Elastic Fabric Adapter (EFA). They are the first EC2 instances to provide multiple network cards.

For more information, see [Amazon EC2 P4d Instances](#).

P4d instances support NVIDIA NVSwitch GPU interconnect and NVIDIA GPUDirect RDMA.

P3 instances

These instances use NVIDIA Tesla V100 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models or through a machine learning framework. P3 instances provide high-bandwidth networking, powerful half, single, and double-precision floating-point capabilities, and up to 32 GiB of memory per GPU, which makes them ideal for deep learning, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads. Tesla V100 GPUs do not support graphics mode.

For more information, see [Amazon EC2 P3 Instances](#).

P3 instances support NVIDIA NVLink peer to peer transfers. For more information, see [NVIDIA NVLink](#).

P2 instances

P2 instances use NVIDIA Tesla K80 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models. P2 instances provide high-bandwidth networking, powerful single and double precision floating-point capabilities, and 12 GiB of memory per GPU, which makes them ideal for deep learning, graph databases, high-performance databases, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads.

P2 instances support NVIDIA GPUDirect peer to peer transfers. For more information, see [NVIDIA GPUDirect](#).

Video transcoding instances

These instances are designed to accelerate video transcoding workloads, such as live broadcast, video conferencing, and just-in-time transcoding.

VT1 instances

VT1 instances feature Xilinx Alveo U30 media accelerators and are designed for live video transcoding workloads. These instances offer up to 8 Xilinx Alveo U30 acceleration cards, provide up to 192 GB of system memory, and up to 25 Gbps of network bandwidth. VT1 instances feature H.264/AVC and H.265/HEVC codecs and support up to 4K UHD resolutions for multi-stream video transcoding.

There are a variety of ways that you can get started:

- Launch a VT1 instance using the Xilinx U30 AMIs on AWS Marketplace.
- Launch a VT1 instance using your own AMI and install the [Xilinx U30 drivers and Xilinx Video SDK](#).
- Launch a container instance using a VT1 instance and an Amazon ECS-optimized AMI.
- Create an Amazon EKS cluster with nodes running VT1 instances.

For more information, see [Amazon EC2 VT1 Instances](#).

Instances with AWS Inferentia

These instances are designed to accelerate machine learning using [AWS Inferentia](#), a custom AI/ML chip from Amazon that provides high performance and low latency machine learning inference. These instances are optimized for deploying deep learning (DL) models for applications, such as natural

language processing, object detection and classification, content personalization and filtering, and speech recognition.

There are a variety of ways that you can get started:

- Use SageMaker, a fully-managed service that is the easiest way to get started with machine learning models. For more information, see [Compile and deploy a TensorFlow model on Inf1 using Sagemaker Neo](#).
- Launch an Inf1 instance using the Deep Learning AMI. For more information, see [AWS Inferentia with DLAMI](#) in the [AWS Deep Learning AMI Developer Guide](#).
- Launch an Inf1 instance using your own AMI and install the [AWS Neuron SDK](#), which enables you to compile, run, and profile deep learning models for AWS Inferentia.
- Launch a container instance using an Inf1 instance and an Amazon ECS-optimized AMI. For more information, see [Amazon Linux 2 \(Inferentia\) AMIs](#) in the [Amazon Elastic Container Service Developer Guide](#).
- Create an Amazon EKS cluster with nodes running Inf1 instances. For more information, see [Inferentia support](#) in the Amazon EKS User Guide.

For more information, see [Machine Learning on AWS](#).

Inf1 instances

Inf1 instances use AWS Inferentia machine learning inference chips. Inferentia was developed to enable highly cost-effective low latency inference performance at any scale.

For more information, see [Amazon EC2 Inf1 Instances](#).

Instances with Habana accelerators

These instances are designed to accelerate deep learning model (DL) training workloads. They use accelerators from Habana Labs, an Intel company. These instances are optimized for DL models for applications such as image recognition, object detection and classification, and recommendation systems.

For more information, see [Machine Learning on AWS](#).

DL1 instances

DL1 instances use Habana Gaudi accelerators. They offer up to 400 Gbps of aggregate network bandwidth, along with 32 GB of high bandwidth memory (HBM) per accelerator. DL1 instances are designed to provide high performance and cost efficiency for training deep learning models.

There are a variety of ways that you can get started:

- Launch a DL1 instance using the [Habana Deep Learning AMI](#).
- Launch a DL1 instance using your own AMI and install the [Habana drivers and Habana SynapseAI SDK](#).
- Launch a container instance using a DL1 instance and an Amazon ECS-optimized AMI.
- Create an Amazon EKS cluster with nodes running DL1 instances.

For more information, see [Amazon EC2 DL1 Instances](#).

FPGA instances

FPGA-based instances provide access to large FPGAs with millions of parallel system logic cells. You can use FPGA-based accelerated computing instances to accelerate workloads such as genomics, financial analysis, real-time video processing, big data analysis, and security workloads by leveraging custom hardware accelerations. You can develop these accelerations using hardware description languages such

as Verilog or VHDL, or by using higher-level languages such as OpenCL parallel computing frameworks. You can either develop your own hardware acceleration code or purchase hardware accelerations through the [AWS Marketplace](#).

The [FPGA Developer AMI](#) provides the tools for developing, testing, and building AFIs. You can use the FPGA Developer AMI on any EC2 instance with at least 32 GB of system memory (for example, C5, M4, and R4 instances).

For more information, see the documentation for the [AWS FPGA Hardware Development Kit](#).

F1 instances

F1 instances use Xilinx UltraScale+ VU9P FPGAs and are designed to accelerate computationally intensive algorithms, such as data-flow or highly parallel operations not suited to general purpose CPUs. Each FPGA in an F1 instance contains approximately 2.5 million logic elements and approximately 6,800 Digital Signal Processing (DSP) engines, along with 64 GiB of local DDR ECC protected memory, connected to the instance by a dedicated PCIe Gen3 x16 connection. F1 instances provide local NVMe SSD volumes.

Developers can use the FPGA Developer AMI and AWS Hardware Developer Kit to create custom hardware accelerations for use on F1 instances. The FPGA Developer AMI includes development tools for full-cycle FPGA development in the cloud. Using these tools, developers can create and share Amazon FPGA Images (AFIs) that can be loaded onto the FPGA of an F1 instance.

For more information, see [Amazon EC2 F1 Instances](#).

For more information about the hardware specifications for each Amazon EC2 instance type, see [Amazon EC2 Instance Types](#).

For more information about specifying CPU options, see [Optimize CPU options \(p. 691\)](#).

Instance performance

There are several GPU setting optimizations that you can perform to achieve the best performance on your instances. For more information, see [Optimize GPU settings \(p. 377\)](#).

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some accelerated computing instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

Some accelerated computing instance types provide the ability to control processor C-states and P-states on Linux. C-states control the sleep levels that a core can enter when it is inactive, while P-states control the desired performance (in CPU frequency) from a core. For more information, see [Processor state control for your EC2 instance \(p. 678\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Linux \(p. 1124\)](#).

The following is a summary of network performance for accelerated computing instances that support enhanced networking.

SSD I/O performance

If you use a Linux AMI with kernel version 4.4 or later and use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
g4ad.xlarge	10,417	8,333
g4ad.2xlarge	20,833	16,667
g4ad.4xlarge	41,667	33,333
g4ad.8xlarge	83,333	66,667
g4ad.16xlarge	166,667	133,333
g5.xlarge	40,625	20,313
g5.2xlarge	40,625	20,313
g5.4xlarge	125,000	62,500
g5.8xlarge	250,000	125,000
g5.12xlarge	312,500	156,250
g5.16xlarge	250,000	125,000
g5.24xlarge	312,500	156,250
g5.48xlarge	625,000	312,500

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the

space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 1635\)](#).

Release notes

- You must launch the instance using an HVM AMI.

- Instances built on the [Nitro System \(p. 247\)](#) have the following requirements:
 - [NVMe drivers \(p. 1558\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1125\)](#) must be installed

The following Linux AMIs meet these requirements:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 (with `linux-aws` kernel) or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- GPU-based instances can't access the GPU unless the NVIDIA drivers are installed. For more information, see [Install NVIDIA drivers on Linux instances \(p. 355\)](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support. Amazon Linux 2 and the latest versions of the Amazon Linux AMI support PCIe native hotplug, but earlier versions do not. You must enable the following Linux kernel configuration options:

```
CONFIG_HOTPLUG_PCI_PCIE=y  
CONFIG_PCIEASPM=y
```

- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- There is a limit of 100 APIs per Region.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Install NVIDIA drivers on Linux instances

An instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, must have the appropriate NVIDIA driver installed. Depending on the instance type, you can either download a public NVIDIA driver, download a driver from Amazon S3 that is available only to AWS customers, or use an AMI with the driver pre-installed.

To install AMD drivers on a Linux instance with an attached AMD GPU, such as a G4ad instance, see [Install AMD drivers \(p. 372\)](#) instead. To install NVIDIA drivers on a Windows instance, see [Install NVIDIA drivers on Windows instances](#).

Types of NVIDIA drivers

The following are the main types of NVIDIA drivers that can be used with GPU-based instances.

Tesla drivers

These drivers are intended primarily for compute workloads, which use GPUs for computational tasks such as parallelized floating-point calculations for machine learning and fast Fourier transforms for high performance computing applications.

GRID drivers

These drivers are certified to provide optimal performance for professional visualization applications that render content such as 3D models or high-resolution videos. You can configure GRID drivers to support two modes. Quadro Virtual Workstations provide access to four 4K displays per GPU. GRID vApps provide RDSH App hosting capabilities.

Gaming drivers

These drivers contain optimizations for gaming and are updated frequently to provide performance enhancements. They support a single 4K display per GPU.

NVIDIA control panel

The NVIDIA control panel is supported with GRID and Gaming drivers. It is not supported with Tesla drivers.

Supported APIs for Tesla, GRID, and gaming drivers

- OpenCL, OpenGL, and Vulkan
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding

Available drivers by instance type

The following table summarizes the supported NVIDIA drivers for each GPU instance type.

Instance type	Tesla driver	GRID driver	Gaming driver
G2	Yes	No	No
G3	Yes	Yes	No
G4dn	Yes	Yes	Yes
G5	Yes	Yes	Yes
G5g	Yes ¹	No	No
P2	Yes	No	No
P3	Yes	Yes ²	No
P4d	Yes	No	No

¹ This Tesla driver also supports optimized graphics applications specific to the ARM64 platform

² Using Marketplace AMIs only

Installation options

Use one of the following options to get the NVIDIA drivers required for your GPU instance.

Option 1: AMIs with the NVIDIA drivers installed

AWS and NVIDIA offer different Amazon Machine Images (AMI) that come with the NVIDIA drivers installed.

- [Marketplace offerings with the Tesla driver](#)
- [Marketplace offerings with the GRID driver](#)
- [Marketplace offerings with the Gaming driver](#)

To update the driver version installed using one of these AMIs, you must uninstall the NVIDIA packages from your instance to avoid version conflicts. Use this command to uninstall the NVIDIA packages:

```
[ec2-user ~]$ sudo yum erase nvidia cuda
```

The CUDA toolkit package has dependencies on the NVIDIA drivers. Uninstalling the NVIDIA packages erases the CUDA toolkit. You must reinstall the CUDA toolkit after installing the NVIDIA driver.

Option 2: Public NVIDIA drivers

The options offered by AWS come with the necessary license for the driver. Alternatively, you can install the public drivers and bring your own license. To install a public driver, download it from the NVIDIA site as described here.

Alternatively, you can use the options offered by AWS instead of the public drivers. To use a GRID driver on a P3 instance, use the AWS Marketplace AMIs as described in [Option 1 \(p. 357\)](#). To use a GRID driver on a G5, G4dn, or G3 instance, use the AWS Marketplace AMIs, as described in Option 1 or install the NVIDIA drivers provided by AWS as described in [Option 3 \(p. 358\)](#).

To download a public NVIDIA driver

Log on to your Linux instance and download the 64-bit NVIDIA driver appropriate for the instance type from <http://www.nvidia.com/Download/Find.aspx>. For **Product Type**, **Product Series**, and **Product**, use the options in the following table.

Instance	Product Type	Product Series	Product
G2	GRID	GRID Series	GRID K520
G3	Tesla	M-Class	M60
G4dn	Tesla	T-Series	T4
G5 ¹	Tesla	A-Series	A10
G5g ²	Tesla	T-Series	NVIDIA T4G
P2	Tesla	K-Series	K80
P3	Tesla	V-Series	V100

Instance	Product Type	Product Series	Product
P4d	Tesla	A-Series	A100

¹ G5 instances require driver version 470.00 or later

² G5g instances require driver version 470.82.01 or later. The operating systems is Linux aarch64

To install the NVIDIA driver on Linux

For more information about installing and configuring the driver, see the [NVIDIA Driver Installation Quickstart Guide](#).

Option 3: GRID drivers (G5, G4dn, and G3 instances)

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA A10G, NVIDIA Tesla T4, or NVIDIA Tesla M60 hardware. Upon installation of the software, you are bound by the terms of the [NVIDIA GRID Cloud End User License Agreement](#).

Prerequisites

- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
- IAM users must have the permissions granted by the **AmazonS3ReadOnlyAccess** policy.
- G5 instances require GRID 13.1 or later (or GRID 12.4 or later).

Amazon Linux and Amazon Linux 2

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

Note

If you are using Amazon Linux 2 with kernel version 5.10, use the following command to install the GRID driver.

```
[ec2-user ~]$ sudo CC=/usr/bin/gcc10-cc ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

10. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

11. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.

- To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#).
- NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in [Activate NVIDIA GRID Virtual Applications \(p. 377\)](#).

CentOS 7 and Red Hat Enterprise Linux 7

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
```

6. Disable the nouveau open source driver for NVIDIA graphics cards.

- a. Add nouveau to the /etc/modprobe.d/blacklist.conf blacklist file. Copy the following code block and paste it into a terminal.

```
[ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

- b. Edit the /etc/default/grub file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

- c. Rebuild the Grub configuration.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

8. Add permissions to run the driver installation utility using the following command.

- b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in [Activate NVIDIA GRID Virtual Applications \(p. 377\)](#).

- c. Install the GUI desktop/workstation package.

```
[ec2-user ~]$ sudo yum groupinstall -y "Server with GUI"
```

CentOS Stream 8 and Red Hat Enterprise Linux 8

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo dnf install -y make gcc elfutils-libelf-devel libglvnd-devel kernel-devel-$(uname -r)
```

6. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .

Ubuntu and Debian

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update -y
```

3. Upgrade the **linux-aws** package to receive the latest version.

```
$ sudo apt-get upgrade -y linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot

7. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

8. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

9. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

10. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2021_10_2.cert"
```

- For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

- For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
```

11. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

12. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#).

Ubuntu and Debian

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update -y
```

3. Upgrade the **linux-aws** package to receive the latest version.

```
$ sudo apt-get upgrade -y linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

5. Reconnect to your instance after it has rebooted.
6. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
$ sudo apt-get install -y gcc make linux-headers-$(uname -r)
```

7. Disable the **nouveau** open source driver for NVIDIA graphics cards.

- a. Add **nouveau** to the **/etc/modprobe.d/blacklist.conf** blacklist file. Copy the following code block and paste it into a terminal.

```
[ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

- b. Edit the /etc/default/grub file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

- c. Rebuild the Grub configuration.

```
$ sudo update-grub
```

8. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

9. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

10. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf
vGamingMarketplace=2
EOF
```

12. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2021_10_2.cert"
```

- For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

- For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#). If you do not require this functionality, do not complete this step.

Install an additional version of CUDA

After you install an NVIDIA graphics driver on your instance, you can install a version of CUDA other than the version that is bundled with the graphics driver. The following procedure demonstrates how to configure multiple versions of CUDA on the instance.

To install the CUDA toolkit

1. Connect to your Linux instance.
2. Open the [NVIDIA website](#) and select the version of CUDA that you need.
3. Select the architecture, distribution, and version for the operating system on your instance. For **Installer Type**, select **runfile (local)**.
4. Follow the instructions to download the install script.
5. Add run permissions to the install script that you downloaded using the following command.

```
[ec2-user ~]$ chmod +x downloaded_installer_file
```

6. Run the install script as follows to install the CUDA toolkit and add the CUDA version number to the toolkit path.

```
[ec2-user ~]$ sudo downloaded_installer_file --silent --override --toolkit --samples --toolkitpath=/usr/local/cuda-version --samplespath=/usr/local/cuda --no-opengl-libs
```

7. (Optional) Set the default CUDA version as follows.

```
[ec2-user ~]$ ln -s /usr/local/cuda-version /usr/local/cuda
```

Install AMD drivers on Linux instances

An instance with an attached AMD GPU, such as a G4ad instance, must have the appropriate AMD driver installed. Depending on your requirements, you can either use an AMI with the driver preinstalled or download a driver from Amazon S3.

To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a G4dn instance, see [Install NVIDIA drivers \(p. 355\)](#) instead. To install AMD drivers on a Windows instance, see [Install AMD drivers on Windows instances](#).

Contents

- [AMD Radeon Pro Software for Enterprise Driver \(p. 373\)](#)
- [AMIs with the AMD driver installed \(p. 373\)](#)

AMD Radeon Pro Software for Enterprise Driver

The AMD Radeon Pro Software for Enterprise Driver is built to deliver support for professional-grade graphics use cases. Using the driver, you can configure your instances with two 4K displays per GPU.

Supported APIs

- OpenGL, OpenCL
- Vulkan
- AMD Advanced Media Framework
- Video Acceleration API

AMIs with the AMD driver installed

AWS offers different Amazon Machine Images (AMI) that come with the AMD drivers installed. Open [Marketplace offerings with the AMD driver](#).

AMD driver download

If you aren't using an AMI with the AMD driver installed, you can download the AMD driver and install it on your instance.

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the AMD Radeon Pro V520 hardware. Upon installation of the software, you are bound by the terms of the [AMD Software End User License Agreement](#).

Prerequisites

- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
- IAM users must have the permissions granted by the [AmazonS3ReadOnlyAccess](#) policy.

To install the AMD driver on your Linux instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

- For Amazon Linux 2:

```
$ sudo amazon-linux-extras install epel -y
$ sudo yum update -y
```

- For Ubuntu:

```
$ sudo dpkg --add-architecture i386
$ sudo apt-get update -y && sudo apt upgrade -y
```

- For CentOS:

```
$ sudo yum install epel-release -y
$ sudo yum update -y
```

3. Reboot the instance.

```
$ sudo reboot
```

4. Reconnect to the instance after it reboots.
5. Download the latest AMD driver.

```
$ aws s3 cp --recursive s3://ec2-amd-linux-drivers/latest/ .
```

6. Extract the file.
- For Amazon Linux 2 and CentOS:

```
$ tar -xf amdgpu-pro-*rhel*.tar.xz
```

- For Ubuntu:

```
$ tar -xf amdgpu-pro*ubuntu*.xz
```

7. Change to the folder for the extracted driver.
 8. Add the GPG keys for the driver installation.
- For Amazon Linux 2 and CentOS:

```
$ sudo rpm --import RPM-GPG-KEY-amdgpu
```

- For Ubuntu:

```
$ sudo apt install linux-modules-extra-$(uname -r) -y
$ cat RPM-GPG-KEY-amdgpu | sudo apt-key add -
```

9. Run the self install script to install the full graphics stack.

```
$ ./amdgpu-pro-install -y --opencl=pal,legacy
```

10. Reboot the instance.

```
$ sudo reboot
```

11. Confirm that the driver is functional.

```
$ dmesg | grep amdgpu
```

The response should look like the following:

```
Initialized amdgpu
```

Set up an interactive desktop

After you confirm that your instance has the AMD GPU driver installed and amdgpu is in use, you can install an interactive desktop manager. We recommend the MATE desktop environment for the best compatibility and performance.

Prerequisite

Open a text editor and save the following as a file named `xorg.conf`. You'll need this file on your instance.

```

To set up an interactive desktop on Amazon Linux 2

1. Install the EPEL repository.

```
$ sudo amazon-linux-extras install epel -y
```

2. Install the MATE desktop.

```
$ sudo amazon-linux-extras install mate-desktop1.x -y  
$ sudo yum groupinstall "MATE Desktop" -y  
$ sudo systemctl disable firewalld
```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
4. Reboot the instance.

```
$ sudo reboot
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.

To set up an interactive desktop on Ubuntu

1. Install the MATE desktop.

```
$ sudo apt install xorg-dev ubuntu-mate-desktop -y  
$ sudo apt purge ifupdown -y
```

2. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
3. Reboot the instance.

```
$ sudo reboot
```

4. Install the AMF encoder for the appropriate version of Ubuntu.

```
$ sudo apt install ./amdgpu-pro-20.20-*/amf-amdgpu-pro_20.20-*_amd64.deb
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.
6. After the DCV installation give the DCV User video permissions:

```
$ sudo usermod -aG video dcv
```

To set up an interactive desktop on CentOS

1. Install the EPEL repository.

```
$ sudo yum update -y  
$ sudo yum install epel-release -y
```

2. Install the MATE desktop.

```
$ sudo yum groupinstall "MATE Desktop" -y  
$ sudo systemctl disable firewalld
```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
4. Reboot the instance.

```
$ sudo reboot
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.

Activate NVIDIA GRID Virtual Applications

To activate the GRID Virtual Applications on G3 and G4dn instances (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver in the /etc/nvidia/gridd.conf file.

To activate GRID Virtual Applications on Linux instances

1. Create the /etc/nvidia/gridd.conf file from the provided template file.

```
[ec2-user ~]$ sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

2. Open the /etc/nvidia/gridd.conf file in your favorite text editor.
3. Find the FeatureType line, and set it equal to 0. Then add a line with IgnoreSP=TRUE.

```
FeatureType=0
IgnoreSP=TRUE
```

4. Save the file and exit.
5. Reboot the instance to pick up the new configuration.

```
[ec2-user ~]$ sudo reboot
```

Optimize GPU settings

There are several GPU setting optimizations that you can perform to achieve the best performance on G3, G4dn, P2, P3, P3dn, and P4d instances. With some of these instance types, the NVIDIA driver uses an autoboot feature, which varies the GPU clock speeds. By disabling autoboot and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances. The following procedure helps you to configure the GPU settings to be persistent, disable the autoboot feature if needed, and set the GPU clock speeds to their maximum frequency.

To optimize GPU settings

1. Configure the GPU settings to be persistent. This command can take several minutes to run.

```
[ec2-user ~]$ sudo nvidia-persistenced
```

2. [G2, G3, and P2 instances only] Disable the autoboot feature for all GPUs on the instance.

```
[ec2-user ~]$ sudo nvidia-smi --auto-boost-default=0
```

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

- G3 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,1177
```

- G4dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 5001,1590
```

- G5 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 6250,1710
```

- P2 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,875
```

- P3 and P3dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 877,1530
```

- P4d instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 1215,1410
```

Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on your requirements for the instances that you'll launch. For example, you might choose an instance type based on the following requirements:

- Availability Zone or Region
- Compute
- Memory
- Networking
- Pricing
- Storage

Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

To find an instance type using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **Instance Types**.
4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select an instance type and view all attributes using the **Details** pane.
5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can list all instance types that have more than eight vCPUs and also support hibernation.

6. (Optional) Select multiple instance types to see a side-by-side comparison across all attributes in the **Details** pane.
7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose **Download list CSV**. The file includes all instance types that match the filters you set.
8. After locating instance types that meet your needs, you can use them to launch instances. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

Find an instance type using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to find an instance type that meet your needs.

To find an instance type using the AWS CLI

1. If you have not done so already, install the AWS CLI. For more information, see the [AWS Command Line Interface User Guide](#).
2. Use the [describe-instance-types](#) command to filter instance types based on instance attributes. For example, you can use the following command to display only instance types with 48 vCPUs.

```
aws ec2 describe-instance-types --filters "Name=vcpu-info.default-vcpus,Values=48" --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

3. Use the [describe-instance-type-offerings](#) command to filter instance types offered by location (Region or Availability Zone). For example, you can use the following command to display the instance types offered in the specified Availability Zone.

```
aws ec2 describe-instance-type-offerings --location-type "availability-zone" --filters Name=location,Values=us-east-2a --region us-east-2
```

4. After locating instance types that meet your needs, make note of them so that you can use these instance types when you launch instances. For more information, see [Launching your instance](#) in the *AWS Command Line Interface User Guide*.

Get recommendations for an instance type

AWS Compute Optimizer provides Amazon EC2 instance recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to move to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance types are best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing.

This topic outlines how to view recommendations through the Amazon EC2 console. For more information, see the [AWS Compute Optimizer User Guide](#).

Note

To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see [Getting Started with AWS Compute Optimizer](#) in the *AWS Compute Optimizer User Guide*.

- [View recommendations \(p. 380\)](#)
- [Considerations for evaluating recommendations \(p. 382\)](#)
- [Additional resources \(p. 382\)](#)

Limitations

Compute Optimizer currently generates recommendations for M, C, R, T, and X instance types. Other instance types are not considered by Compute Optimizer. If you're using other instance types, they will not be listed in the Compute Optimizer recommendations view. For information about these and other instance types, see [Instance types \(p. 240\)](#).

Findings

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.
- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.
- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.
- **None** – There are no recommendations for this instance. This might occur if you've been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer. For more information, see [Limitations \(p. 380\)](#) in the previous section.

View recommendations

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.

New console

To view a recommendation for an EC2 instance through the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then choose the instance ID.
3. On the instance summary page, in the **AWS Compute Optimizer** banner near the bottom of the page, choose **View detail**.

The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose the settings () icon to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

Note

If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Old console

To view a recommendation for an EC2 instance through the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and on the **Description** tab, inspect the **Finding** field. Choose **View detail**.

The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose the settings () icon to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

Note

If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Determine whether you want to use one of the recommendations. Decide whether to optimize for performance improvement, for cost reduction, or for a combination of the two. For more information, see [Viewing Resource Recommendations](#) in the *AWS Compute Optimizer User Guide*.

To view recommendations for all EC2 instances across all Regions through the Compute Optimizer console

1. Open the Compute Optimizer console at <https://console.aws.amazon.com/compute-optimizer/>.
2. Choose **View recommendations for all EC2 instances**.
3. You can perform the following actions on the recommendations page:
 - a. To filter recommendations to one or more AWS Regions, enter the name of the Region in the **Filter by one or more Regions** text box, or choose one or more Regions in the drop-down list that appears.
 - b. To view recommendations for resources in another account, choose **Account**, and then select a different account ID.

This option is available only if you are signed in to a management account of an organization, and you opted in all member accounts within the organization.

- c. To clear the selected filters, choose **Clear filters**.
- d. To change the purchasing option that is displayed for the current and recommended instance

types, choose the settings () icon , and then choose **On-Demand Instances**, **Reserved Instances, standard 1-year no upfront**, or **Reserved Instances, standard 3-year no upfront**.

- e. To view details, such as additional recommendations and a comparison of utilization metrics, choose the finding (**Under-provisioned**, **Over-provisioned**, or **Optimized**) listed next to the desired instance. For more information, see [Viewing Resource Details](#) in the *AWS Compute Optimizer User Guide*.

Considerations for evaluating recommendations

Before changing an instance type, consider the following:

- The recommendations don't forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.
- Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see [Viewing Available Metrics](#) in the *Amazon CloudWatch User Guide*.
- Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see [Key concepts and definitions for burstable performance instances \(p. 268\)](#).
- If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.
- Consider conversions to newer generation instances, where possible.
- When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see [Compatibility for changing the instance type \(p. 387\)](#).
- Finally, consider the performance risk rating that's provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

There are other considerations when resizing an EC2 instance. For more information, see [Change the instance type \(p. 382\)](#).

Change the instance type

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your `t2.micro` instance is too small for its workload, you can increase its size by changing it to a bigger T2 instance type, such as `t2.large`. Or you can change it to another instance type, such as `m5.large`. You might also want to change from a previous generation to a current generation instance type to take advantage of some features, such as support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see [Get recommendations for an instance type \(p. 379\)](#).

Which instructions to follow?

There are different instructions for changing the instance type. The instructions to use depend on the instance's root volume, and whether the instance type is compatible with the instance's current configuration. For information about how compatibility is determined, see [Compatibility for changing the instance type \(p. 387\)](#).

Use the following table to determine which instructions to follow.

Root volume	Compatibility	Use these instructions
EBS	Compatible	Change the instance type of an existing EBS-backed instance (p. 383)
EBS	Not compatible	Change the instance type by launching a new instance (p. 385)
Instance store	Not applicable	Change the instance type of an instance store-backed instance (p. 388)

Considerations for compatible instance types

Consider the following when changing the instance type of an existing instance:

- You must stop your Amazon EBS-backed instance before you can change its instance type. Ensure that you plan for downtime while your instance is stopped. Stopping the instance and changing its instance type might take a few minutes, and restarting your instance might take a variable amount of time depending on your application's startup scripts. For more information, see [Stop and start your instance \(p. 637\)](#).
- When you stop and start an instance, we move the instance to new hardware. If your instance has a public IPv4 address, we release the address and give your instance a new public IPv4 address. If you require a public IPv4 address that does not change, use an [Elastic IP address \(p. 1082\)](#).
- You can't change the instance type if [hibernation \(p. 640\)](#) is enabled for the instance.
- You can't change the instance type of a [Spot Instance \(p. 461\)](#).
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you're changing the instance type. For more information, see [Suspending and resuming a process for an Auto Scaling group](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you change the instance type of an instance with NVMe instance store volumes, the updated instance might have additional instance store volumes, because all NVMe instance store volumes are available even if they are not specified in the AMI or instance block device mapping. Otherwise, the updated instance has the same number of instance store volumes that you specified when you launched the original instance.

Change the instance type of an existing EBS-backed instance

Use the following instructions to change the instance type of an EBS-backed instance if the instance type that you need is compatible with the instance's current configuration.

New console

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see [Compatibility for changing the instance type \(p. 387\)](#).
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. Select the instance and choose **Instance state, Stop instance**. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance settings, Change instance type**. This option is grayed out if the instance state is not stopped.
6. On the **Change instance type** page, do the following:
 - a. For **Instance type**, select the instance type that you want.

If the instance type is not in the list, then it's not compatible with the configuration of your instance. Instead, use the following instructions: [Change the instance type by launching a new instance \(p. 385\)](#).
 - b. (Optional) If the instance type that you selected supports EBS optimization, select **EBS-optimized** to enable EBS optimization, or deselect **EBS-optimized** to disable EBS optimization. If the instance type that you selected is EBS optimized by default, **EBS-optimized** is selected and you can't deselect it.
 - c. Choose **Apply** to accept the new settings.
7. To start the instance, select the instance and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the `running` state. If your instance won't start, see [Troubleshoot changing the instance type \(p. 388\)](#).

Old console

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see [Compatibility for changing the instance type \(p. 387\)](#).
2. Open the Amazon EC2 console.
3. In the navigation pane, choose **Instances**.
4. Select the instance and choose **Actions, Instance State, Stop**. When prompted for confirmation, choose **Yes, Stop**.

It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance Settings, Change Instance Type**. This action is grayed out if the instance state is not stopped.
6. In the **Change Instance Type** dialog box, do the following:
 - a. From **Instance Type**, select the instance type that you want.

If the instance type that you want does not appear in the list, then it is not compatible with the configuration of your instance. Instead, use the following instructions: [Change the instance type by launching a new instance \(p. 385\)](#).
 - b. (Optional) If the instance type that you selected supports EBS–optimization, select **EBS-optimized** to enable EBS–optimization or deselect **EBS-optimized** to disable EBS–

- optimization. If the instance type that you selected is EBS–optimized by default, **EBS-optimized** is selected and you can't deselect it.
- c. Choose **Apply** to accept the new settings.
 7. To restart the stopped instance, select the instance and choose **Actions, Instance State, Start**.
 8. In the confirmation dialog box, choose **Yes, Start**. It can take a few minutes for the instance to enter the `running` state. If your instance won't start, see [Troubleshoot changing the instance type \(p. 388\)](#).

Change the instance type by launching a new instance

If the current configuration of your EBS-backed instance is incompatible with the new instance type that you want, then you can't change the instance type of the original instance. Instead, you must launch a new instance with a configuration that is compatible with the new instance type that you want, and then migrate your application to the new instance. For example, if you launched your original instance from a PV AMI, but want to change to a current generation instance type that is only supported by an HVM AMI, you'll need to launch a new instance from an HVM AMI. For information about how compatibility is determined, see [Compatibility for changing the instance type \(p. 387\)](#).

To migrate your application to a new instance, do the following:

- Back up the data on your original instance.
- Launch a new instance with a configuration that is compatible with the new instance type that you want, and attach any EBS volumes that were attached to your original instance.
- Install your application and any software on your new instance.
- Restore any data.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see [Elastic IP address \(p. 1082\)](#).

New console

To change the instance type for a new instance configuration

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Back up data that you need to keep, as follows:
 - For data on your instance store volumes, back up the data to persistent storage.
 - For data on your EBS volumes, [take a snapshot of the volumes \(p. 1407\)](#) or [detach the volumes from the instance \(p. 1400\)](#) so that you can attach them to the new instance later.
3. In the navigation pane, choose **Instances**.
4. Choose **Launch instances**. When you configure the instance, do the following:
 - a. Select an AMI that will support the instance type that you want. Note that current generation instance types require an HVM AMI.
 - b. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you selected.
 - c. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.
 - d. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
 - e. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.

5. If required, [attach any new EBS volumes \(p. 1375\)](#) based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.
6. Install your application and any required software on the new instance.
7. Restore any data that you backed up from the instance store volumes of the original instance.
8. If you are using an Elastic IP address, assign it to the new instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
 - c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.
 - d. For **Resource type**, choose **Instance**.
 - e. For **Instance**, choose the new instance with which to associate the Elastic IP address.
 - f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
 - g. Choose **Associate**.
9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.

Old console

To migrate your application to a compatible instance

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, create a snapshot of the volumes (see [Create Amazon EBS snapshots \(p. 1407\)](#)) or detach the volume from the instance so that you can attach it to the new instance later (see [Detach an Amazon EBS volume from a Linux instance \(p. 1400\)](#)).
2. Launch a new instance, selecting the following:
 - An HVM AMI.
 - The HVM only instance type.
 - If you are using an Elastic IP address, select the VPC that the original instance is currently running in.
 - Any EBS volumes that you detached from the original instance and want to attach to the new instance, or new EBS volumes based on the snapshots that you created.
 - If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
3. Install your application and any required software on the instance.
4. Restore any data that you backed up from the instance store volumes of the original instance.
5. If you are using an Elastic IP address, assign it to the newly launched instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate address**. When prompted for confirmation, choose **Disassociate address**.
 - c. With the Elastic IP address still selected, choose **Actions, Associate address**.
 - d. From **Instance**, select the new instance, and then choose **Associate**.
6. (Optional) You can terminate the original instance if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose **Actions, Instance State, Terminate**.

Compatibility for changing the instance type

You can change the instance type only if the instance's current configuration is compatible with the instance type that you want. If the instance type that you want is not compatible with the instance's current configuration, you must launch a new instance with a configuration that is compatible with the instance type, and then migrate your application to the new instance.

Compatibility is determined in the following ways:

Virtualization type

Linux AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). If an instance was launched from a PV AMI, you can't change to an instance type that is HVM only. For more information, see [Linux AMI virtualization types \(p. 108\)](#). To check the virtualization type of your instance, check the **Virtualization** value on the details pane of the **Instances** screen in the Amazon EC2 console.

Architecture

AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:

- If the current instance type has a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
- The following instance types are the only instance types that support 32-bit AMIs: t2.nano, t2.micro, t2.small, t2.medium, c3.large, t1.micro, m1.small, m1.medium, and c1.medium. If you are changing the instance type of a 32-bit instance, you are limited to these instance types.

Network

Newer instance types must be launched in a VPC. Therefore, if the instance is in the EC2-Classic platform, you can't change the instance type to one that is available only in a VPC unless you have a nondefault VPC. To check whether your instance is in a VPC, check the **VPC ID** value on the details pane of the **Instances** screen in the Amazon EC2 console. For more information, see [Migrate from EC2-Classic to a VPC \(p. 1226\)](#).

Network cards

Some instance types support multiple [network cards \(p. 1093\)](#). You must select an instance type that supports the same number of network cards as the current instance type.

Enhanced networking

Instance types that support [enhanced networking \(p. 1124\)](#) require the necessary drivers installed. For example, instances based on the [Nitro System \(p. 247\)](#) require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To change from an instance type that does not support enhanced networking to an instance type that supports enhanced networking, you must install the [ENA drivers \(p. 1125\)](#) or [ixgbevf drivers \(p. 1134\)](#) on the instance, as appropriate.

NVMe

EBS volumes are exposed as NVMe block devices on instances built on the [Nitro System \(p. 247\)](#). If you change from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the [NVMe drivers \(p. 1558\)](#) on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (`/dev/nvme[0-26]n1`). Therefore, to mount file systems at boot time using `/etc/fstab`, you must use UUID/Label instead of device names.

AMI

For information about the AMIs required by instance types that support enhanced networking and NVMe, see the Release Notes in the following documentation:

- [General purpose instances \(p. 251\)](#)
- [Compute optimized instances \(p. 308\)](#)
- [Memory optimized instances \(p. 319\)](#)
- [Storage optimized instances \(p. 335\)](#)

Troubleshoot changing the instance type

Use the following information to help diagnose and fix issues that you might encounter when changing the instance type.

Instance won't start after changing instance type

Possible cause: Requirements for new instance type not met

If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see [Why is my Linux instance not booting after I changed its type?](#)

Possible cause: AMI does not support instance type

If you use the EC2 console to change the instance type, only the instance types that are supported by the selected AMI are available. However, if you use the AWS CLI to launch an instance, you can specify an incompatible AMI and instance type. If the AMI and instance type are incompatible, the instance can't start. For more information, see [Compatibility for changing the instance type \(p. 387\)](#).

Possible cause: Instance is in cluster placement group

If your instance is in a [cluster placement group \(p. 1191\)](#) and, after changing the instance type, the instance fails to start, try the following:

1. Stop all the instances in the cluster placement group.
2. Change the instance type of the affected instance.
3. Start all the instances in the cluster placement group.

Application or website not reachable from the internet after changing instance type

Possible cause: Public IPv4 address is released

When you change the instance type, you must first stop the instance. When you stop an instance, we release the public IPv4 address and give your instance a new public IPv4 address.

To retain the public IPv4 address between instance stops and starts, we recommend that you use an Elastic IP address, at no extra cost provided your instance is running. For more information, see [Elastic IP addresses \(p. 1082\)](#).

Change the instance type of an instance store-backed instance

An instance store-backed instance is an instance that has an instance store root volume. You can't change the instance type of an instance that has an instance store root volume. Instead, you must create an AMI from your instance, launch a new instance from this AMI and select the instance type that you want, and then migrate your application to the new instance. Note that the instance type that you want must be compatible with the AMI you create. For information about how compatibility is determined, see [Compatibility for changing the instance type \(p. 387\)](#).

To migrate your application to a new instance, do the following:

- Back up the data on your original instance.
- Create an AMI from your original instance.
- Launch a new instance from this AMI and select the instance type that you want.
- Install your application on the new instance.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see [Elastic IP address \(p. 1082\)](#).

New console

To change the instance type of an instance store-backed instance

1. Back up data that you need to keep, as follows:
 - For data on your instance store volumes, back up the data to persistent storage.
 - For data on your EBS volumes, [take a snapshot of the volumes \(p. 1407\)](#) or [detach the volume from the instance \(p. 1400\)](#) so that you can attach it to the new instance later.
2. Create an AMI from your instance by satisfying the prerequisites and following the procedures in [Create an instance store-backed Linux AMI \(p. 149\)](#). When you are finished creating an AMI from your instance, return to this procedure.
3. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
4. In the navigation pane, choose **AMIs**. From the filter lists, choose **Owned by me**, and select the image that you created in Step 2. Notice that **AMI name** is the name that you specified when you registered the image and **Source** is your Amazon S3 bucket.

Note

If you do not see the AMI that you created in Step 2, make sure that you have selected the Region in which you created your AMI.

5. With the AMI selected, choose **Launch instance from image**. When you configure the instance, do the following:
 - a. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you created. For more information, see [Compatibility for changing the instance type \(p. 387\)](#).
 - b. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.
 - c. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
 - d. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.
6. If required, [attach any new EBS volumes \(p. 1375\)](#) based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.
7. Install your application and any required software on the new instance.
8. If you are using an Elastic IP address, assign it to the new instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
 - c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.
 - d. For **Resource type**, choose **Instance**.
 - e. For **Instance**, choose the new instance with which to associate the Elastic IP address.

- f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
- g. Choose **Associate**.
9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.

Old console

To migrate an instance store-backed instance

1. Back up any data on your instance store volumes that you need to keep to persistent storage. To migrate data on your EBS volumes that you need to keep, take a snapshot of the volumes (see [Create Amazon EBS snapshots \(p. 1407\)](#)) or detach the volume from the instance so that you can attach it to the new instance later (see [Detach an Amazon EBS volume from a Linux instance \(p. 1400\)](#)).
2. Create an AMI from your instance store-backed instance by satisfying the prerequisites and following the procedures in [Create an instance store-backed Linux AMI \(p. 149\)](#). When you are finished creating an AMI from your instance, return to this procedure.
3. Open the Amazon EC2 console and in the navigation pane, choose **AMIs**. From the filter lists, choose **Owned by me**, and choose the image that you created in the previous step. Notice that **AMI Name** is the name that you specified when you registered the image and **Source** is your Amazon S3 bucket.

Note

If you do not see the AMI that you created in the previous step, make sure that you have selected the Region in which you created your AMI.

4. Choose **Launch**. When you specify options for the instance, be sure to select the new instance type that you want. If the instance type that you want can't be selected, then it is not compatible with configuration of the AMI that you created (for example, because of virtualization type). You can also specify any EBS volumes that you detached from the original instance.

It can take a few minutes for the instance to enter the `running` state.

5. (Optional) You can terminate the instance that you started with, if it's no longer needed. Select the instance and verify that you are about to terminate the original instance, not the new instance (for example, check the name or launch time). Choose **Actions, Instance State, Terminate**.

Instance purchasing options

Amazon EC2 provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay, by the second, for the instances that you launch.
- **Savings Plans** – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- **Reserved Instances** – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- **Spot Instances** – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- **Dedicated Hosts** – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- **Dedicated Instances** – Pay, by the hour, for instances that run on single-tenant hardware.

- **Capacity Reservations** – Reserve capacity for your EC2 instances in a specific Availability Zone for any duration.

If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses. For more information, see [Amazon EC2 Pricing](#).

For more information about Savings Plans, see the [Savings Plans User Guide](#).

Determine the instance lifecycle

The lifecycle of an instance starts when it is launched and ends when it is terminated. The purchasing option that you choose affects the lifecycle of the instance. For example, an On-Demand Instance runs when you launch it and ends when you terminate it. A Spot Instance runs as long as capacity is available and your maximum price is higher than the Spot price.

Use the following procedure to determine the lifecycle of an instance.

New console

To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Lifecycle**. If the value is **spot**, the instance is a Spot Instance. If the value is **normal**, the instance is either an On-Demand Instance or a Reserved Instance.
5. On the **Details** tab, under **Host and placement group**, find **Tenancy**. If the value is **host**, the instance is running on a Dedicated Host. If the value is **dedicated**, the instance is a Dedicated Instance.
6. (Optional) If you have purchased a Reserved Instance and want to verify that it is being applied, you can check the usage reports for Amazon EC2. For more information, see [Amazon EC2 usage reports \(p. 1708\)](#).

Old console

To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Description** tab, find **Tenancy**. If the value is `host`, the instance is running on a Dedicated Host. If the value is `dedicated`, the instance is a Dedicated Instance.
5. On the **Description** tab, find **Lifecycle**. If the value is `spot`, the instance is a Spot Instance. If the value is `normal`, the instance is either an On-Demand Instance or a Reserved Instance.
6. (Optional) If you have purchased a Reserved Instance and want to verify that it is being applied, you can check the usage reports for Amazon EC2. For more information, see [Amazon EC2 usage reports \(p. 1708\)](#).

To determine the instance lifecycle using the AWS CLI

Use the following `describe-instances` command:

```
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

If the instance is running on a Dedicated Host, the output contains the following information:

```
"Tenancy": "host"
```

If the instance is a Dedicated Instance, the output contains the following information:

```
"Tenancy": "dedicated"
```

If the instance is a Spot Instance, the output contains the following information:

```
"InstanceLifecycle": "spot"
```

Otherwise, the output does not contain `InstanceLifecycle`.

On-Demand Instances

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over its lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the `running` state. The price per second for a running On-Demand Instance is fixed, and is listed on the [Amazon EC2 Pricing, On-Demand Pricing page](#).

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use [AWS Savings Plans](#), [Spot Instances \(p. 439\)](#), or [Reserved Instances \(p. 396\)](#).

Work with On-Demand Instances

You can work with On-Demand Instances in the following ways:

- Launch your instance (p. 578)
- Connect to your Linux instance (p. 611)
- Stop and start your instance (p. 637)
- Hibernate your On-Demand Linux instance (p. 640)
- Reboot your instance (p. 657)

- Terminate your instance (p. 661)
- Recover your instance (p. 667)
- Configure your Amazon Linux instance (p. 669)
- Identify EC2 Linux instances (p. 776)

If you're new to Amazon EC2, see [How to get started with Amazon EC2 \(p. 1\)](#).

On-Demand Instance limits

There is a limit on the number of running On-Demand Instances per AWS account per Region. On-Demand Instance limits are managed in terms of the *number of virtual central processing units (vCPUs)* that your running On-Demand Instances are using, regardless of the instance type.

There are eight On-Demand Instance limits:

- Running On-Demand Standard (A, C, D, H, I, M, R, T, Z) instances
- Running On-Demand DL instances
- Running On-Demand F instances
- Running On-Demand G and VT instances
- Running On-Demand High Memory instances
- Running On-Demand Inf instances
- Running On-Demand P instances
- Running On-Demand X instances

Each limit specifies the vCPU limit for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account limit. For example, with a Standard instance limit of 256 vCPUs, you could launch 32 m5.2xlarge instances (32 x 8 vCPUs) or 16 c5.4xlarge instances (16 x 16 vCPUs). For more information, see [EC2 On-Demand Instance limits](#).

Monitor On-Demand Instance limits and usage

You can view and manage your On-Demand Instance limits using the following:

- The [Limits page](#) in the Amazon EC2 console
- The Amazon EC2 [Services quotas page](#) in the Service Quotas console
- The [get-service-quota](#) AWS CLI
- The [Service limits page](#) in the AWS Trusted Advisor console

For more information, see [Amazon EC2 service quotas \(p. 1706\)](#) in the *Amazon EC2 User Guide*, [Viewing service quotas](#) in the *Service Quotas User Guide*, and [AWS Trusted Advisor](#).

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against limits. You can also configure alarms to warn about approaching limits. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Calculate how many vCPUs you need

You can use the vCPU limits calculator to determine the number of vCPUs that you require for your application needs.

When using the calculator, keep the following in mind: The calculator assumes that you have reached your current limit. The value that you enter for **Instance count** is the number of instances that you need to launch *in addition* to what is permitted by your current limit. The calculator adds your current limit to the **Instance count** to arrive at a new limit.

The following screenshot shows the vCPU limits calculator.

The screenshot shows a web-based calculator titled "Limits Calculator". It has a header stating: "Use this tool to calculate how many vCPUs you need to launch your On-Demand Instances". Below this, a note says: "Select the instance type and the number of instances you require. The calculator will display the number of vCPUs assigned to the selected instances. Use the New Limit value as a guide for requesting a limit increase." The main interface consists of two tables. The first table, "Instance type", lists three instances: m5.2xlarge (32), c5.4xlarge (16), and f1.16xlarge (2). The second table, "Limits calculation", shows the current limit for each instance type and provides a "Request limit increase" link. A "Close" button is at the bottom right.

Instance type	Instance count	vCPU count	Current limit	New limit
m5.2xlarge	32	256 vCPUs	2,016 vCPUs	2,272 vCPUs
c5.4xlarge	16	256 vCPUs	2,016 vCPUs	2,272 vCPUs
f1.16xlarge	2	128 vCPUs	176 vCPUs	304 vCPUs

Instance limit name	Current limit	vCPUs needed	New limit	Options
All Standard (A, C, D, H, I, M, R, T, Z) instances	2,016 vCPUs	512 vCPUs	2,528 vCPUs	Request limit increase
All F instances	176 vCPUs	128 vCPUs	304 vCPUs	Request limit increase

You can view and use the following controls and information:

- **Instance type** – The instance types that you add to the vCPU limits calculator.

- **Instance count** – The number of instances that you require for the selected instance type.
- **vCPU count** – The number of vCPUs that corresponds to the **Instance count**.
- **Current limit** – Your current limit for the limit type to which the instance type belongs. The limit applies to all instance types of the same limit type. For example, in the preceding screenshot, the current limit for `m5.2xlarge` and `c5.4xlarge` is 2,016 vCPUs, which is the limit for all the instance types that belong to the All Standard instances limit.
- **New limit** – The new limit, in number of vCPUs, which is calculated by adding **vCPU count** and **Current limit**.
- **X** – Choose the **X** to remove the row.
- **Add instance type** – Choose **Add instance type** to add another instance type to the calculator.
- **Limits calculation** – Displays the current limit, vCPUs needed, and new limit for the limit types.
 - **Instance limit name** – The limit type for the instance types that you selected.
 - **Current limit** – The current limit for the limit type.
 - **vCPUs needed** – The number of vCPUs that corresponds to the number of instances that you specified in **Instance count**. For the All Standard instances limit type, the vCPUs needed is calculated by adding the values for **vCPU count** for all the instance types of this limit type.
 - **New limit** – The new limit is calculated by adding **Current limit** and **vCPUs needed**.
- **Options** – Choose **Request limit increase** to request a limit increase for the corresponding limit type.

To calculate the number of required vCPUs

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select a Region.
3. From the left navigator, choose **Limits**.
4. Choose **Calculate vCPU limit**.
5. Choose **Add instance type**, choose the required instance type, and specify the required number of instances. To add more instance types, choose **Add instance type** again.
6. View **Limits calculation** for the required new limit.
7. When you've finished using the calculator, you can choose **Request on-demand limit increase** or **Close**.

Request a limit increase

Even though Amazon EC2 automatically increases your On-Demand Instance limits based on your usage, you can request a limit increase if necessary. For example, if you intend to launch more instances than your current limit allows, you can request a limit increase.

To request an On-Demand Instance limit increase

1. Open the **Create case, Service limit increase** form in the Support Center console at <https://console.aws.amazon.com/support/home#/case/create>.

Alternatively, use one of the following:

 - From the **Limits Calculator**, choose one or more instance types and specify the number of instances, and then choose **Request on-demand limit increase**.
 - On the **Limits** page, choose a limit, and then choose **Request limit increase**.
2. For **Limit type**, choose **EC2 Instances**.
3. For **Region**, select the required Region.

4. For **Primary instance type**, select the On-Demand Instance limit for which you want to request a limit increase.
5. For **New limit value**, enter the total number of vCPUs that you want to run concurrently. To determine the total number of vCPUs that you need, use the value that appears in the **New limit** column in the vCPU limits calculator, or see [Amazon EC2 Instance Types](#) to find the number of vCPUs of each instance type.
6. (Conditional) You must create a separate limit request for each On-Demand Instance limit. To request an increase for another On-Demand Instance limit, choose **Add another request** and repeat steps 3 through 5 in this procedure.
7. For **Use case description**, enter your use case, and then choose **Submit**.

For more information about requesting a limit increase, see [Amazon EC2 service quotas \(p. 1706\)](#).

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see [Using the AWS Price List API](#) in the *AWS Billing and Cost Management User Guide*.

Reserved Instances

Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

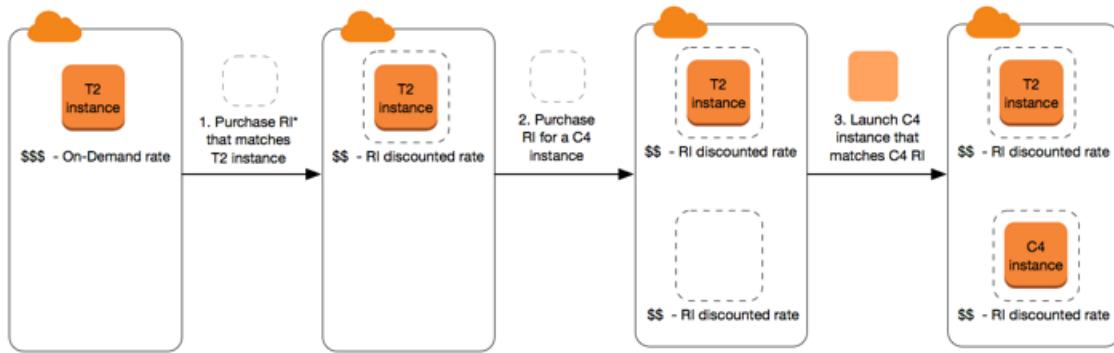

Savings Plans also offer significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. With Savings Plans, you make a commitment to a consistent usage amount, measured in USD per hour. This provides you with the flexibility to use the instance configurations that best meet your needs and continue to save money, instead of making a commitment to a specific instance configuration. For more information, see the [AWS Savings Plans User Guide](#).

Reserved Instance overview

The following diagram shows a basic overview of purchasing and using Reserved Instances.

*RI = Reserved Instance

In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

Key variables that determine Reserved Instance pricing

The Reserved Instance pricing is determined by the following key variables.

Instance attributes

A Reserved Instance has four instance attributes that determine its price.

- **Instance type:** For example, `m4.large`. This is composed of the instance family (for example, `m4`) and the instance size (for example, `large`).
- **Region:** The Region in which the Reserved Instance is purchased.
- **Tenancy:** Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see [Dedicated Instances \(p. 531\)](#).
- **Platform:** The operating system; for example, Windows or Linux/Unix. For more information, see [Choosing a platform \(p. 412\)](#).

Term commitment

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year:** A year is defined as 31536000 seconds (365 days).
- **Three-year:** Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.

Payment options

The following payment options are available for Reserved Instances:

- **All Upfront:** Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront:** A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront:** You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

Note

No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.

Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see [Sell in the Reserved Instance Marketplace \(p. 419\)](#).

Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard:** These provide the most significant discount, but can only be modified. Standard Reserved Instances can't be exchanged.
- **Convertible:** These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see [Types of Reserved Instances \(offering classes\) \(p. 399\)](#).

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify \(p. 426\)](#), [exchange \(p. 433\)](#), or [sell \(p. 419\)](#) your Reserved Instance if your needs change.

For more information, see the [Amazon EC2 Reserved Instances Pricing page](#).

Regional and zonal Reserved Instances (scope)

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional:** When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.
- **Zonal:** When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.

The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see [Key variables that determine Reserved Instance pricing \(p. 397\)](#) and [Amazon EC2 Reserved Instances Pricing](#).

Differences between regional and zonal Reserved Instances

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

	Regional Reserved Instances	Zonal Reserved Instances
Ability to reserve capacity	A regional Reserved Instance does <i>not</i> reserve capacity.	A zonal Reserved Instance reserves capacity in the specified Availability Zone.
Availability Zone flexibility	The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.	No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.
Instance size flexibility	<p>The Reserved Instance discount applies to instance usage within the instance family, regardless of size.</p> <p>Only supported on Amazon Linux/Unix Reserved Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor (p. 401).</p>	No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.
Queuing a purchase	You can queue purchases for regional Reserved Instances.	You can't queue purchases for zonal Reserved Instances.

For more information and examples, see [How Reserved Instances are applied \(p. 400\)](#).

Types of Reserved Instances (offering classes)

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

Differences between Standard and Convertible Reserved Instances

The following are the differences between Standard and Convertible Reserved Instances.

	Standard Reserved Instance	Convertible Reserved Instance
Modify Reserved Instances	Some attributes can be modified. For more information, see Modify Reserved Instances (p. 426) .	Some attributes can be modified. For more information, see Modify Reserved Instances (p. 426) .
Exchange Reserved Instances	Can't be exchanged.	Can be exchanged during the term for another Convertible Reserved Instance with new attributes, including instance family, instance type, platform, scope, or tenancy.

	Standard Reserved Instance	Convertible Reserved Instance
		For more information, see Exchange Convertible Reserved Instances (p. 433) .
Sell in the Reserved Instance Marketplace	Can be sold in the Reserved Instance Marketplace.	Can't be sold in the Reserved Instance Marketplace.
Buy in the Reserved Instance Marketplace	Can be bought in the Reserved Instance Marketplace.	Can't be bought in the Reserved Instance Marketplace.

How Reserved Instances are applied

Reserved Instances are not physical instances, but rather a billing discount that is applied to the running On-Demand Instances in your account. The On-Demand Instances must match certain specifications of the Reserved Instances in order to benefit from the billing discount.

If you purchase a Reserved Instance and you already have a running On-Demand Instance that matches the specifications of the Reserved Instance, the billing discount is applied immediately and automatically. You do not have to restart your instances. If you do not have an eligible running On-Demand Instance, launch an On-Demand Instance with the same specifications as your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 406\)](#).

The offering class (Standard or Convertible) of the Reserved Instance does not affect how the billing discount is applied.

Topics

- [How zonal Reserved Instances are applied \(p. 400\)](#)
- [How regional Reserved Instances are applied \(p. 400\)](#)
- [Instance size flexibility \(p. 401\)](#)
- [Examples of applying Reserved Instances \(p. 403\)](#)

How zonal Reserved Instances are applied

A Reserved Instance that is purchased to reserve capacity in a specific Availability Zone is called a zonal Reserved Instance.

- The Reserved Instance discount applies to matching instance usage in that Availability Zone.
- The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

For example, if you purchase two c4.xlarge default tenancy Linux/Unix Standard Reserved Instances for Availability Zone us-east-1a, then up to two c4.xlarge default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount.

How regional Reserved Instances are applied

A Reserved Instance that is purchased for a Region is called a regional Reserved Instance, and provides Availability Zone and instance size flexibility.

- The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.
- The Reserved Instance discount applies to instance usage within the instance family, regardless of size —this is known as [instance size flexibility \(p. 401\)](#).

Instance size flexibility

With instance size flexibility, the Reserved Instance discount applies to instance usage within the instance family. The Reserved Instance is applied from the smallest to the largest instance size within the instance family based on the normalization factor. For an example of how the Reserved Instance discount is applied, see [Scenario 2: Reserved Instances in a single account using the normalization factor \(p. 404\)](#).

Limitations

Instance size flexibility applies only to Regional Reserved Instances.

Instance size flexibility does not apply to the following Reserved Instances:

- Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
- Reserved Instances with dedicated tenancy
- Reserved Instances for Windows Server, Windows Server with SQL Standard, Windows Server with SQL Server Enterprise, Windows Server with SQL Server Web, RHEL, and SUSE Linux Enterprise Server
- Reserved Instances for G4dn instances

Instance size flexibility determined by normalization factor

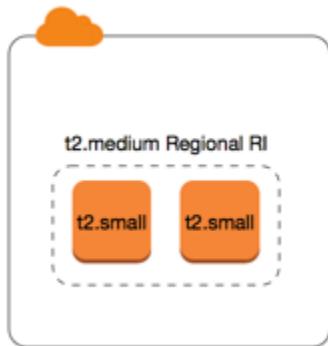

Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

The following table lists the different sizes within an instance family, and the corresponding normalization factor. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

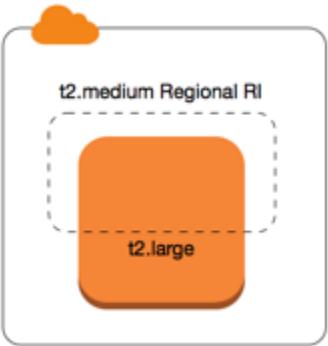

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64
9xlarge	72
10xlarge	80

Instance size	Normalization factor
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
56xlarge	448
112xlarge	896

For example, a `t2.medium` instance has a normalization factor of 2. If you purchase a `t2.medium` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running `t2.small` instances in your account in that Region, the billing benefit is applied in full to both instances.

Or, if you have one `t2.large` instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.

The normalization factor is also applied when modifying Reserved Instances. For more information, see [Modify Reserved Instances \(p. 426\)](#).

Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if

If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The `metal` instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an `i3.metal` instance has the same normalization factor as an `i3.16xlarge` instance.

Instance size	Normalization factor
<code>a1.metal</code>	32
<code>m5zn.metal z1d.metal</code>	96
<code>c6g.metal c6gd.metal i3.metal m6g.metal m6gd.metal r6g.metal r6gd.metal x2gd.metal</code>	128
<code>c5n.metal</code>	144
<code>c5.metal c5d.metal i3en.metal m5.metal m5d.metal m5dn.metal m5n.metal r5.metal r5b.metal r5d.metal r5dn.metal r5n.metal</code>	192
<code>u-* .metal</code>	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running `i3.16xlarge` in your account in that Region, the billing benefit is applied in full to the `i3.16xlarge` instance (`i3.16xlarge` normalization factor = 128).
- Or, if you have two running `i3.8xlarge` instances in your account in that Region, the billing benefit is applied in full to both `i3.8xlarge` instances (`i3.8xlarge` normalization factor = 64).
- Or, if you have four running `i3.4xlarge` instances in your account in that Region, the billing benefit is applied in full to all four `i3.4xlarge` instances (`i3.4xlarge` normalization factor = 32).

The opposite is also true. For example, if you purchase two `i3.8xlarge` default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running `i3.metal` instance in that Region, the billing benefit is applied in full to the `i3.metal` instance.

Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

- [Scenario 1: Reserved Instances in a single account \(p. 403\)](#)
- [Scenario 2: Reserved Instances in a single account using the normalization factor \(p. 404\)](#)
- [Scenario 3: Regional Reserved Instances in linked accounts \(p. 405\)](#)
- [Scenario 4: Zonal Reserved Instances in a linked account \(p. 405\)](#)

Scenario 1: Reserved Instances in a single account

You are running the following On-Demand Instances in account A:

- 4 x `m3.large` Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x `m4.xlarge` Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x `c4.xlarge` Amazon Linux, default tenancy instances in Availability Zone us-east-1c

You purchase the following Reserved Instances in account A:

- 4 x m3.1large Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x m4.1large Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x c4.1large Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four m3.1large zonal Reserved Instances is used by the four m3.1large instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The m4.1large regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

An m4.1large is equivalent to 4 normalized units/hour.

You've purchased four m4.1large regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two m4.xlarge instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four m4.1large regional Reserved Instances provide the billing benefit to an entire hour of usage of the two m4.xlarge instances.

- The c4.1large regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the c4.xlarge instance. A c4.1large instance is equivalent to 4 normalized units/hour and a c4.xlarge is equivalent to 8 normalized units/hour.

In this case, the c4.1large regional Reserved Instance provides partial benefit to c4.xlarge usage. This is because the c4.1large Reserved Instance is equivalent to 4 normalized units/hour of usage, but the c4.xlarge instance requires 8 normalized units/hour. Therefore, the c4.1large Reserved Instance billing discount applies to 50% of c4.xlarge usage. The remaining c4.xlarge usage is charged at the On-Demand rate.

Scenario 2: Reserved Instances in a single account using the normalization factor

You are running the following On-Demand Instances in account A:

- 2 x m3.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m3.1large Amazon Linux, default tenancy instances in Availability Zone us-east-1b

You purchase the following Reserved Instance in account A:

- 1 x m3.2xlarge Amazon Linux, default tenancy Reserved Instance in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The m3.2xlarge regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy. It applies first to the m3.1large instances and then to the m3.xlarge instances, because it applies from the smallest to the largest instance size within the instance family based on the normalization factor.

An m3.1large instance is equivalent to 4 normalized units/hour.

An m3.xlarge instance is equivalent to 8 normalized units/hour.

An m3.2xlarge instance is equivalent to 16 normalized units/hour.

The benefit is applied as follows:

The `m3.2xlarge` regional Reserved Instance provides full benefit to `2 x m3.large` usage, because together these instances account for 8 normalized units/hour. This leaves 8 normalized units/hour to apply to the `m3.xlarge` instances.

With the remaining 8 normalized units/hour, the `m3.2xlarge` regional Reserved Instance provides full benefit to `1 x m3.xlarge` usage, because each `m3.xlarge` instance is equivalent to 8 normalized units/hour. The remaining `m3.xlarge` usage is charged at the On-Demand rate.

Scenario 3: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see [Reserved Instances and consolidated billing \(p. 409\)](#). For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

- `2 x m4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a
- `1 x m4.2xlarge` Linux, default tenancy instances in Availability Zone us-east-1b
- `2 x c4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a
- `1 x c4.2xlarge` Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

- `2 x m4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

- `4 x m4.xlarge` Linux, default tenancy Reserved Instances in Region us-east-1
- `2 x c4.xlarge` Linux, default tenancy Reserved Instances in Region us-east-1

The regional Reserved Instance benefits are applied in the following way:

- The discount of the four `m4.xlarge` Reserved Instances is used by the two `m4.xlarge` instances and the single `m4.2xlarge` instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two `m4.xlarge` that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
- The discount of the two `c4.xlarge` Reserved Instances applies to the two `c4.xlarge` instances, because they are a smaller instance size than the `c4.2xlarge` instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

Scenario 4: Zonal Reserved Instances in a linked account

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x m4.xlarge Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x m4.xlarge Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the m4.xlarge zonal Reserved Instance owned by account C is applied to the m4.xlarge usage in account A.
- The discount of the m4.xlarge regional Reserved Instance owned by account A is applied to the m4.xlarge usage in account B.
- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see [Reserved Instances in the Billing and Cost Management Report](#).

Use your Reserved Instances

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an On-Demand Instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information when you configure your On-Demand Instance:

Platform

You must specify an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified Linux/UNIX for your Reserved Instance, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

Instance type

If you purchased a zonal Reserved Instance, you must specify the same instance type as your Reserved Instance; for example, t3.large. For more information, see [How zonal Reserved Instances are applied \(p. 400\)](#).

If you purchased a regional Reserved Instance, you must specify an instance type from the same instance family as the instance type of your Reserved Instance. For example, if you specified t3.xlarge for your Reserved Instance, you must launch your instance from the T3 family, but you can specify any size, for example, t3.medium. For more information, see [How regional Reserved Instances are applied \(p. 400\)](#).

Availability Zone

If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone.

If you purchased a regional Reserved Instance, you can launch the instance into any Availability Zone in the Region that you specified for the Reserved Instance.

Tenancy

The tenancy (dedicated or shared) of the instance must match the tenancy of your Reserved Instance. For more information, see [Dedicated Instances \(p. 531\)](#).

For examples of how Reserved Instances are applied to your running On-Demand Instances, see [How Reserved Instances are applied \(p. 400\)](#). For more information, see [Why aren't my Amazon EC2 Reserved Instances applying to my AWS billing in the way that I expected?](#)

You can use various methods to launch the On-Demand Instances that use your Reserved Instance discount. For information about the different launch methods, see [Launch your instance \(p. 578\)](#). You can also use Amazon EC2 Auto Scaling to launch an instance. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

How you are billed

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the [payment option \(p. 397\)](#) specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see [Queue your purchase \(p. 412\)](#).

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged under standard pricing guidelines. For information, see [AWS Free Tier](#).

Usage billing

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see [Instance lifecycle \(p. 574\)](#).

A Reserved Instance billing benefit can be applied to a running instance on a per-second basis. Per-second billing is available for instances using an open-source Linux distribution, such as Amazon Linux and Ubuntu. Per-hour billing is used for commercial Linux distributions, such as Red Hat Enterprise Linux and SUSE Linux Enterprise Server.

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the

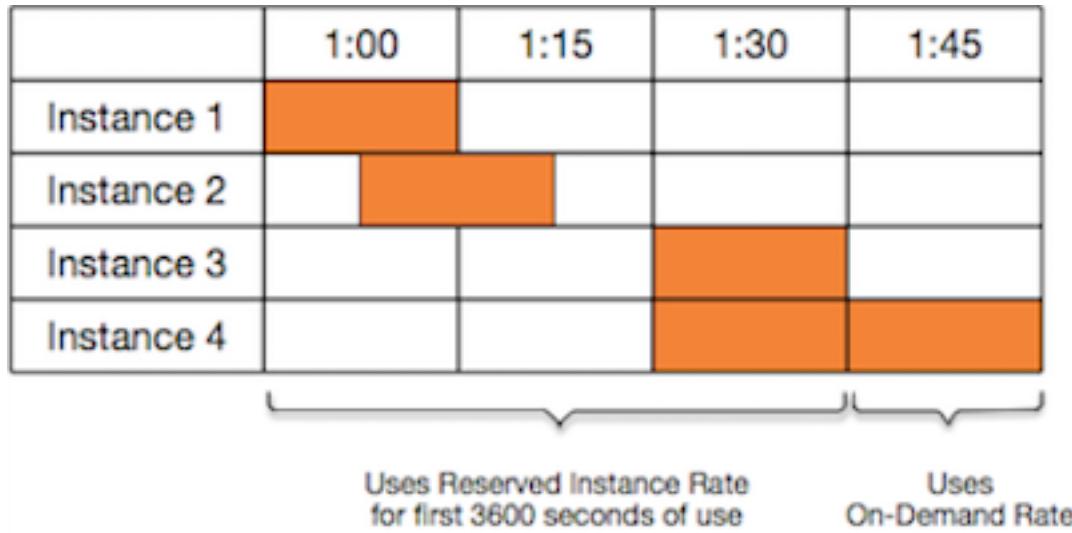

Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

	1:00	1:15	1:30	1:45
Instance 1	Orange			
Instance 2		Orange		
Instance 3			Orange	
Instance 4				Orange

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.

Cost Explorer on the [Billing and Cost Management](#) console enables you to analyze the savings against running On-Demand Instances. The [Reserved Instances FAQ](#) includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.

Viewing your bill

You can find out about the charges and fees to your account by viewing the [AWS Billing and Cost Management](#) console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details** expand the **Elastic Compute Cloud** section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see [Reserved Instances](#) under Cost and Usage Report in the *AWS Billing and Cost Management User Guide*.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see [Consolidated billing for AWS Organizations](#).

If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved Instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be \$500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

```
List value = fixed price + (undiscounted recurring hourly price * hours in term)
```

For example, for a 1-year Partial Upfront t2.small Reserved Instance, assume the upfront price is \$60.00 and the hourly rate is \$0.007. This provides a list value of \$121.32.

```
121.32 = 60.00 + (0.007 * 8760)
```

New console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. To display the **Upfront price** column, choose the settings icon () in the top-right corner, toggle on **Upfront price**, and choose **Confirm**.

Buy with a discount tier

When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can buy Reserved Instances using any of the Amazon EC2 tools. For more information, see [Buy Reserved Instances \(p. 411\)](#).

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more information about the temporary Reserved Instance IDs that are created during the purchase process, see [Crossing pricing tiers \(p. 411\)](#).

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount**—Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.

Crossing pricing tiers

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

Consolidated billing for pricing tiers

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see [Reserved Instances and consolidated billing \(p. 409\)](#).

Buy Reserved Instances

To purchase a Reserved Instance, search for *Reserved Instance offerings* from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. If, at the time of purchase, there are offerings similar to your choice but at a lower price, AWS sells you the offerings at the lower price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase.

Note

To purchase and modify Reserved Instances, ensure that your IAM user account has the appropriate permissions, such as the ability to describe Availability Zones. For information, see [Example Policies for Working With the AWS CLI or an AWS SDK](#) and [Example Policies for Working in the Amazon EC2 Console](#).

Choosing a platform

Amazon EC2 supports the following Linux platforms for Reserved Instances:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- Red Hat Enterprise Linux with HA

When you purchase a Reserved Instance, you must choose an offering for a *platform* that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, you must choose offerings for those specific platforms, i.e., for the **SUSE Linux** or **Red Hat Enterprise Linux** platforms.
- For all other Linux distributions (including Ubuntu), choose an offering for the **Linux/UNIX** platform.
- If you bring your existing RHEL subscription, you must choose an offering for the **Linux/UNIX** platform, not an offering for the **Red Hat Enterprise Linux** platform.

Important

If you plan to purchase a Reserved Instance to apply to an On-Demand Instance that was launched from an AWS Marketplace AMI, first check the `PlatformDetails` field of the AMI. The `PlatformDetails` field indicates which Reserved Instance to purchase. The platform details of the AMI must match the platform of the Reserved Instance, otherwise the Reserved Instance will not be applied to the On-Demand Instance. For information about how to view the platform details of the AMI, see [Understand AMI billing information \(p. 207\)](#).

For information about the supported platforms for Windows, see [Choosing a platform](#) in the *Amazon EC2 User Guide for Windows Instances*.

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can queue a purchase for around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is **queued**. You can cancel a queued purchase any time before its scheduled time. For details, see [Cancel a queued purchase \(p. 418\)](#).

Buy Standard Reserved Instances

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

New console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed, and then choose **Search**.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose **Add to cart**.

- To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd party** in the **Seller** column in the search results. The **Term** column displays non-standard terms. For more information, see [Buy from the Reserved Instance Marketplace \(p. 417\)](#).
7. To see a summary of the Reserved Instances that you selected, choose **View cart**.
 8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
 9. To complete the order, choose **Order all**.

- If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.
10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

Note

If the status goes to **Retired**, AWS might not have received your payment.

Old console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.

5. Select other configurations as needed and choose **Search**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd Party** in the **Seller** column in the search results. The **Term** column displays non-standard terms.

6. For each Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of the Reserved Instances that you selected, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **payment-pending** to **active**. When the Reserved Instance is active, it is ready to use.

Note

If the status goes to **retired**, AWS might not have received your payment.

To buy a Standard Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the [describe-reserved-instances-offerings](#) command. Specify **standard** for the **--offering-class** parameter to return only Standard Reserved Instances. You can apply additional parameters to narrow your results. For example, if you want to purchase a regional **t2.large** Reserved Instance with a default tenancy for **Linux/UNIX** for a 1-year term only:

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class standard \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=duration,Values=31536000 Name=scope,Values=Region
```

To find Reserved Instances on the Reserved Instance Marketplace only, use the **marketplace** filter and do not specify a duration in the request, as the term might be shorter than a 1- or 3-year term.

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class standard \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=marketplace,Values=true
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 406\)](#).

For examples of how Reserved Instances are applied to your running instances, see [How Reserved Instances are applied \(p. 400\)](#).

Buy Convertible Reserved Instances

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

New console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.

5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.
7. To see a summary of your selection, choose **View cart**.

8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

Note

If the status goes to **Retired**, AWS might not have received your payment.

Old console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of your selection, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **payment-pending** to **active**. When the Reserved Instance is **active**, it is ready to use.

Note

If the status goes to **retired**, AWS might not have received your payment.

To buy a Convertible Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the `describe-reserved-instances-offerings` command. Specify `convertible` for the `--offering-class` parameter to return only Convertible Reserved Instances. You can apply additional parameters to narrow your results; for example, if you want to purchase a regional `t2.large` Reserved Instance with a default tenancy for `Linux/UNIX`:

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class convertible \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=scope,Values=Region
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 406\)](#).

For examples of how Reserved Instances are applied to your running instances, see [How Reserved Instances are applied \(p. 400\)](#).

Buy from the Reserved Instance Marketplace

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see [Buy Standard Reserved Instances \(p. 413\)](#).

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:

- **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.

- **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer's purchase invoice. If you need additional information about the seller for tax or related reasons, contact [AWS Support](#).

[View your Reserved Instances](#)

You can view the Reserved Instances you've purchased using the Amazon EC2 console, or a command line tool.

To view your Reserved Instances in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Your queued, active, and retired Reserved Instances are listed. The **State** column displays the state.
4. If you are a seller in the Reserved Instance Marketplace, the **My Listings** tab displays the status of a reservation that's listed in the [Reserved Instance Marketplace \(p. 419\)](#). For more information, see [Reserved Instance listing states \(p. 424\)](#).

To view your Reserved Instances using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (Tools for Windows PowerShell)

[Cancel a queued purchase](#)

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.

New console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete queued Reserved Instances**.
5. When prompted for confirmation, choose **Delete**, and then **Close**.

Old console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete Queued Reserved Instances**.
5. When prompted for confirmation, choose **Yes, Delete**.

To cancel a queued purchase using the command line

- [delete-queued-reserved-instances](#) (AWS CLI)
- [Remove-EC2QueuedReservedInstance](#) (Tools for Windows PowerShell)

Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

New console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order all**, and then **Close**.

Old console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order**.

Sell in the Reserved Instance Marketplace

The Reserved Instance Marketplace is a platform that supports the sale of third-party and AWS customers' unused Standard Reserved Instances, which vary in term lengths and pricing options. For example, you might want to sell Reserved Instances after moving instances to a new AWS Region, changing to a new instance type, ending projects before the term expiration, when your business needs change, or if you have unneeded capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.

To fulfill a buyer's request, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see [Buy from the Reserved Instance Marketplace \(p. 417\)](#).

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see [Register as a seller \(p. 421\)](#).

The following limitations and restrictions apply when selling Reserved Instances:

- Only Amazon EC2 Standard Reserved Instances can be sold in the Reserved Instance Marketplace. Amazon EC2 Convertible Reserved Instances cannot be sold. Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold.
- There must be at least one month remaining in the term of the Standard Reserved Instance.
- You cannot sell a Standard Reserved Instance in a Region that is [disabled by default](#).
- The minimum price allowed in the Reserved Instance Marketplace is \$0.00.
- You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace as long as they have been active in your account for at least 30 days. Additionally, if there is an upfront payment on a Reserved Instance, it can only be sold after AWS has received the upfront payment.
- You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see [Price your Reserved Instances \(p. 422\)](#). You can also modify your Reserved Instances before listing them. For information, see [Modify Reserved Instances \(p. 426\)](#).
- You can't sell regional Reserved Instances via the console. To list a regional Reserved Instance in the marketplace, you must first modify the scope to zonal.

- AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.
- When you register as a seller, the bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.
- Amazon Internet Services Private Limited (AISPL) customers can't sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see [What are the differences between AWS accounts and AISPL accounts?](#)

Register as a seller

Note

Only the AWS account root user can register an account as a seller.

To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

- **Bank information**—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see [Bank account for disbursement \(p. 421\)](#).
- **Tax information**—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see [Tax information \(p. 422\)](#).

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.

To register a default bank account for disbursements

1. Open the [Reserved Instance Marketplace Seller Registration](#) page and sign in using your AWS credentials.
2. On the **Manage Bank Account** page, provide the following information about the bank through to receive payment:
 - Bank account holder name
 - Routing number
 - Account number
 - Bank account type

Note

If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).

After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the [Reserved Instance Marketplace Seller Registration](#) page, sign in with the account that you used when you registered.
2. On the **Manage Bank Account** page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the [Seller Registration Portal](#). The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see the [IRS website](#).

Price your Reserved Instances

The upfront fee is the only fee that you can specify for the Reserved Instance that you're selling. The upfront fee is the one-time fee that the buyer pays when they purchase a Reserved Instance.

The following are important limits to note:

- **You can sell up to \$50,000 in Reserved Instances.** To increase this limit, complete the [EC2 Reserved Instance Sales](#) form.
- **You can sell up to 5,000 Reserved Instances.** To increase this limit, complete the [EC2 Reserved Instance Sales](#) form.
- **The minimum price is \$0.** The minimum allowed price in the Reserved Instance Marketplace is \$0.00.

You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

You can cancel your listing at any time, as long as it's in the active state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells.

For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

List your Reserved Instances

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than \$1.01, the suggested price is \$1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

To list a Reserved Instance in the Reserved Instance Marketplace using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instances to list, and choose **Actions, Sell Reserved Instances**.
4. On the **Configure Your Reserved Instance Listing** page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the **Months Remaining** column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose **Reset**.
6. Choose **Continue** when you are finished configuring your listing.
7. Confirm the details of your listing, on the **Confirm Your Reserved Instance Listing** page and if you're satisfied, choose **List Reserved Instance**.

To view your listings in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance that you've listed and choose the **My Listings** tab near the bottom of the page.

To manage Reserved Instances in the Reserved Instance Marketplace using the AWS CLI

1. Get a list of your Reserved Instances by using the [describe-reserved-instances](#) command.
2. Note the ID of the Reserved Instance you want to list and call [create-reserved-instances-listing](#). You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the [describe-reserved-instances-listings](#) command.

4. To cancel your listing, use the [cancel-reserved-instances-listings](#) command.

Reserved Instance listing states

Listing State on the **My Listings** tab of the Reserved Instances page displays the current status of your listings:

The information displayed by **Listing State** is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the **State** column in the **Reserved Instances** page. This **State** information is about your reservation.

- **active**—The listing is available for purchase.
- **canceled**—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- **closed**—The Reserved Instance is not listed. A Reserved Instance might be **closed** because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the **My Listings** tab shows that the **Total instance count** matches the count listed under **Sold**. Also, there are no **Available** instances left for your listing, and its **Status** is **closed**.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as **closed**.

For example, you create a listing *Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample* with a listing count of 5.

The **My Listings** tab in the **Reserved Instance** console page displays the listing this way:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.

This is how your listing looks in the **My Listings** tab:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 2
- Available = 3

- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

After your Reserved Instance is sold

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

To track the status of a Reserved Instance listing in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation page, choose **Reserved Instances**.
3. Choose the **My Listings** tab.

The **My Listings** tab contains the **Listing State** value. It also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

You can also use the [describe-reserved-instances-listings](#) command with the appropriate filter to obtain information about your listings.

Getting paid

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

Information shared with the buyer

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls AWS Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, [contact AWS Support](#).

Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone, instance size (within the same instance family), and scope of your Reserved Instance.

Note

You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see [Exchange Convertible Reserved Instances \(p. 433\)](#).

You can modify all or a subset of your Reserved Instances. You can separate your original Reserved Instances into two or more new Reserved Instances. For example, if you have a reservation for 10 instances in `us-east-1a` and decide to move 5 instances to `us-east-1b`, the modification request results in two new reservations: one for 5 instances in `us-east-1a` and the other for 5 instances in `us-east-1b`.

You can also *merge* two or more Reserved Instances into a single Reserved Instance. For example, if you have four `t2.small` Reserved Instances of one instance each, you can merge them to create one `t2.large` Reserved Instance. For more information, see [Support for modifying instance sizes \(p. 428\)](#).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the [describe-reserved-instances](#) command.
- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.
- The modified reservation lists a \$0 fixed price and not the fixed price of the original reservation.
- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

- [Support for modifying instance sizes \(p. 428\)](#)
- [Submit modification requests \(p. 431\)](#)
- [Troubleshoot modification requests \(p. 432\)](#)

Requirements and restrictions for modification

You can modify these attributes as follows.

Modifiable attribute	Supported platforms	Limitations
Change Availability Zones within the same Region	Linux and Windows	-
Change the scope from Availability Zone to Region and vice versa	Linux and Windows	If you change the scope from Availability Zone to Region, you lose the capacity reservation benefit. If you change the scope from Region to Availability Zone, you lose Availability Zone flexibility and instance size flexibility (if applicable). For more information, see How Reserved Instances are applied (p. 400) .
Change the instance size within the same instance family	Linux/UNIX only Instance size flexibility is not available for Reserved Instances on the other platforms, which include Linux with SQL Server Standard, Linux with SQL Server Web, Linux with SQL Server Enterprise, Red Hat Enterprise Linux, SUSE Linux, Windows, Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web.	The reservation must use default tenancy. Some instance families are not supported, because there are no other sizes available. For more information, see Support for modifying instance sizes (p. 428) .
Change the network from EC2-Classic to Amazon VPC and vice versa	Linux and Windows	The network platform must be available in your AWS account. If you created your AWS account after 2013-12-04, it does not support EC2-Classic.

Requirements

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
- There cannot be a pending modification request
- The Reserved Instance is not listed in the Reserved Instance Marketplace
- There must be a match between the instance size footprint of the original reservation and the new configuration. For more information, see [Support for modifying instance sizes \(p. 428\)](#).
- The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type

- The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances
- The Reserved Instance is not a G4 instance.

Support for modifying instance sizes

You can modify the instance size of a Reserved Instance if the following requirements are met.

Requirements

- The platform is Linux/UNIX.
- You must select another instance size in the same instance family. For example, you cannot modify an Reserved Instance from t2 to t3, whether you use the same size or a different size.

You cannot modify the instance size of Reserved Instances for the following instances, because each of these instance families has only one size:

- cc2.8xlarge
- cr1.8xlarge
- hs1.8xlarge
- t1.micro
- The original and new Reserved Instance must have the same instance size footprint.

Contents

- [Instance size footprint \(p. 428\)](#)
- [Normalization factors for bare metal instances \(p. 430\)](#)

Instance size footprint

Each Reserved Instance has an *instance size footprint*, which is determined by the normalization factor of the instance size and the number of instances in the reservation. When you modify the instance sizes in an Reserved Instance, the footprint of the new configuration must match that of the original configuration, otherwise the modification request is not processed.

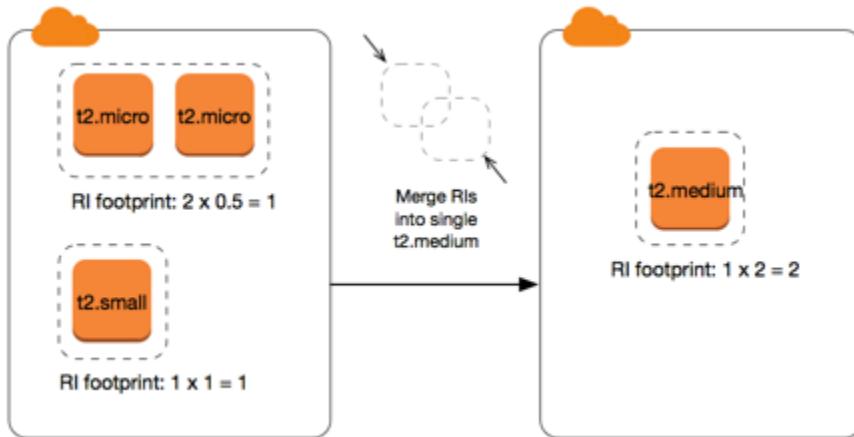

To calculate the instance size footprint of a Reserved Instance, multiply the number of instances by the normalization factor. In the Amazon EC2 console, the normalization factor is measured in units. The following table describes the normalization factor for the instance sizes in an instance family. For example, t2.medium has a normalization factor of 2, so a reservation for four t2.medium instances has a footprint of 8 units.

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16

Instance size	Normalization factor
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64
9xlarge	72
10xlarge	80
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
56xlarge	448
112xlarge	896

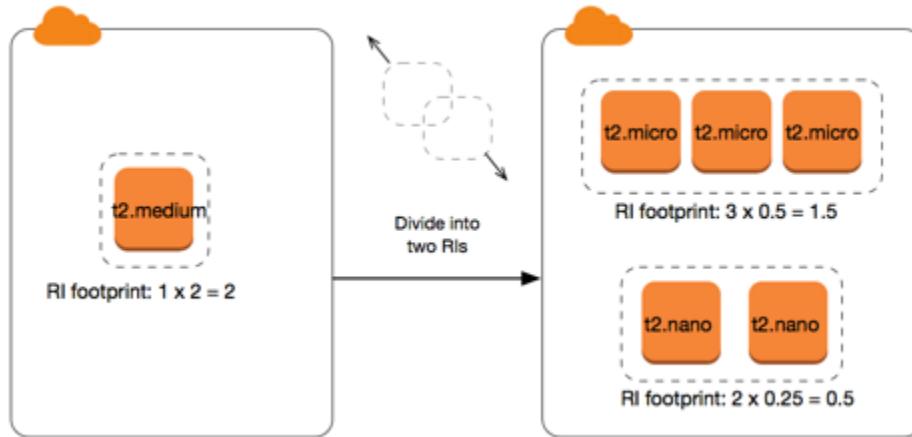

You can allocate your reservations into different instance sizes across the same instance family as long as the instance size footprint of your reservation remains the same. For example, you can divide a reservation for one `t2.large` (1 @ 4 units) instance into four `t2.small` (4 @ 1 unit) instances. Similarly, you can combine a reservation for four `t2.small` instances into one `t2.large` instance. However, you cannot change your reservation for two `t2.small` instances into one `t2.large` instance because the footprint of the new reservation (4 units) is larger than the footprint of the original reservation (2 units).

In the following example, you have a reservation with two `t2.micro` instances (1 unit) and a reservation with one `t2.small` instance (1 unit). If you merge both of these reservations to a single reservation with one `t2.medium` instance (2 units), the footprint of the new reservation equals the footprint of the combined reservations.

You can also modify a reservation to divide it into two or more reservations. In the following example, you have a reservation with a `t2.medium` instance (2 units). You can divide the reservation into two

reservations, one with two t2.nano instances (.5 units) and the other with three t2.micro instances (1.5 units).

Normalization factors for bare metal instances

You can modify a reservation with `metal` instances using other sizes within the same instance family. Similarly, you can modify a reservation with instances other than bare metal instances using the `metal` size within the same instance family. Generally, a bare metal instance is the same size as the largest available instance size within the same instance family. For example, an `i3.metal` instance is the same size as an `i3.16xlarge` instance, so they have the same normalization factor.

The following table describes the normalization factor for the bare metal instance sizes in the instance families that have bare metal instances. The normalization factor for `metal` instances depends on the instance family, unlike the other instance sizes.

Instance size	Normalization factor
<code>a1.metal</code>	32
<code>m5zn.metal z1d.metal</code>	96
<code>c6g.metal c6gd.metal i3.metal m6g.metal m6gd.metal r6g.metal r6gd.metal x2gd.metal</code>	128
<code>c5n.metal</code>	144
<code>c5.metal c5d.metal i3en.metal m5.metal m5d.metal m5dn.metal m5n.metal r5.metal r5b.metal r5d.metal r5dn.metal r5n.metal</code>	192
<code>u-* .metal</code>	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance, you can divide the reservation as follows:

- An `i3.16xlarge` is the same size as an `i3.metal` instance, so its normalization factor is 128 (128/1). The reservation for one `i3.metal` instance can be modified into one `i3.16xlarge` instance.
- An `i3.8xlarge` is half the size of an `i3.metal` instance, so its normalization factor is 64 (128/2). The reservation for one `i3.metal` instance can be divided into two `i3.8xlarge` instances.
- An `i3.4xlarge` is a quarter the size of an `i3.metal` instance, so its normalization factor is 32 (128/4). The reservation for one `i3.metal` instance can be divided into four `i3.4xlarge` instances.

Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable [restrictions \(p. 427\)](#). Before you modify the instance size, calculate the total [instance size footprint \(p. 428\)](#) of the original reservations that you want to modify and ensure that it matches the total instance size footprint of your new configurations.

New console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.

Note

If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.

3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration.
 - **Scope:** Choose whether the configuration applies to an Availability Zone or to the whole Region.
 - **Availability Zone:** Choose the required Availability Zone. Not applicable for regional Reserved Instances.
 - **Instance type:** Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
 - **Count:** Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.
4. Choose **Continue**.
5. To confirm your modification choices when you finish specifying your target configurations, choose **Submit modifications**.
6. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.
 - **active (pending modification)** — Transition state for original Reserved Instances
 - **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
 - **retired** — Reserved Instances successfully modified and replaced
 - **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

Old console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

Note

If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.

3. The first entry in the modification table displays attributes of selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration, and then choose **Continue**:
 - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
 - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
 - **Instance Type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
 - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.
4. To confirm your modification choices when you finish specifying your target configurations, choose **Submit Modifications**.
5. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.
 - **active (*pending modification*)** — Transition state for original Reserved Instances
 - **retired (*pending modification*)** — Transition state for original Reserved Instances while new Reserved Instances are being created
 - **retired** — Reserved Instances successfully modified and replaced
 - **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

To modify your Reserved Instances using the command line

1. To modify your Reserved Instances, you can use one of the following commands:
 - [modify-reserved-instances](#) (AWS CLI)
 - [Edit-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)
2. To get the status of your modification request (*processing*, *fulfilled*, or *failed*), use one of the following commands:
 - [describe-reserved-instances-modifications](#) (AWS CLI)
 - [Get-EC2ReservedInstancesModification](#) (AWS Tools for Windows PowerShell)

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request. Ensure that you have read the applicable [restrictions \(p. 427\)](#) before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the **Reserved Instances** page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

Exchange Convertible Reserved Instances

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the original Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.

You can't exchange Standard Reserved Instances, but you can modify them. For more information, see [Modify Reserved Instances \(p. 426\)](#).

- [Exchange a portion of a Convertible Reserved Instance \(p. 436\)](#)
- [Submit exchange requests \(p. 437\)](#)

Requirements for exchanging Convertible Reserved Instances

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:

- Active
- Not pending a previous exchange request

The following rules apply:

- Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.

- Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
- You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
- To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see [Exchange a portion of a Convertible Reserved Instance \(p. 436\)](#). For more information about modifying your Reserved Instances, see [Modify Reserved Instances \(p. 426\)](#).
- All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

Note

If the total upfront payment required for the exchange (true-up cost) is less than \$0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is \$0.00 or more.

Note

If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.
- You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.
- You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.

Note

If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.
- If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see [Merge Convertible Reserved Instances \(p. 435\)](#).
- After you exchange a Convertible Reserved Instance, the original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Convertible Reserved Instance. For example, if you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.

Calculate Convertible Reserved Instances exchanges

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the original Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.

Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x \$35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of \$10.

$$\$35/\$10 = 3.5$$

You can exchange your Convertible Reserved Instance for three \$10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

$$3.5 = 3 \text{ whole Convertible Reserved Instances} + 1 \text{ additional Convertible Reserved Instance}$$

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is \$500, and the new reservation would normally cost \$600 on a prorated basis, you are charged \$100.

$$\$600 \text{ prorated upfront cost of new reservations} - \$500 \text{ remaining upfront cost of original reservations} = \$100 \text{ difference}$$

Merge Convertible Reserved Instances

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the original Convertible Reserved Instances, or the highest of the original Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.

For example, you have the following Convertible Reserved Instances in your account:

Reserved Instance ID	Term	Expiration date
aaaa1111	1-year	2018-12-31
bbbb2222	1-year	2018-07-31
cccc3333	3-year	2018-06-30
dddd4444	3-year	2019-12-31

- You can merge `aaaa1111` and `bbbb2222` and exchange them for a 1-year Convertible Reserved Instance. You cannot exchange them for a 3-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-12-31.
- You can merge `bbbb2222` and `cccc3333` and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.
- You can merge `cccc3333` and `dddd4444` and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

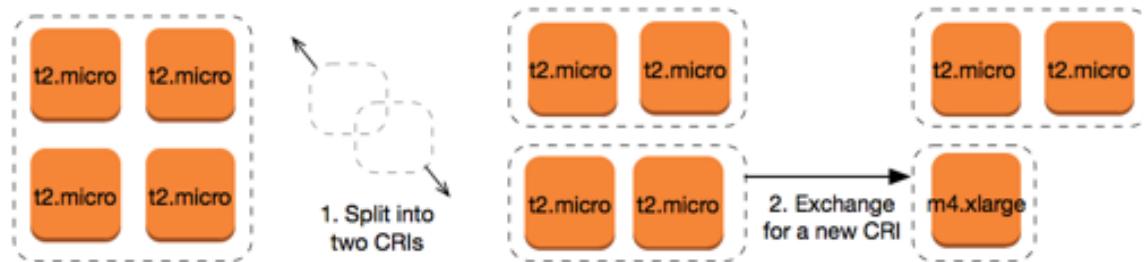

Exchange a portion of a Convertible Reserved Instance

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

Example Example: Convertible Reserved Instance with multiple instances

In this example, you have a `t2.micro` Convertible Reserved Instance with four instances in the reservation. To exchange two `t2.micro` instances for an `m4.xlarge` instance:

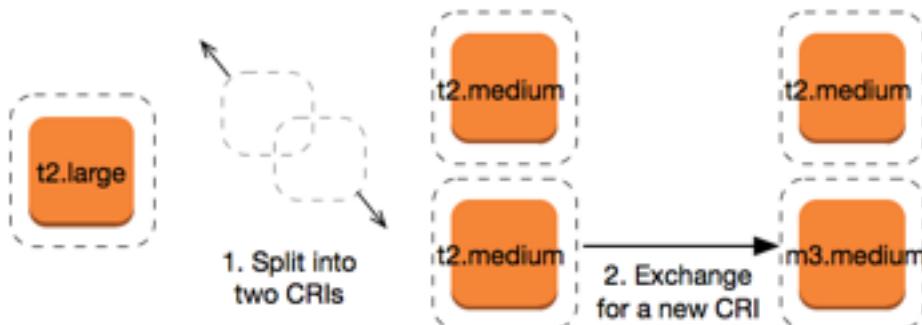

1. Modify the `t2.micro` Convertible Reserved Instance by splitting it into two `t2.micro` Convertible Reserved Instances with two instances each.
2. Exchange one of the new `t2.micro` Convertible Reserved Instances for an `m4.xlarge` Convertible Reserved Instance.

Example Example: Convertible Reserved Instance with a single instance

In this example, you have a `t2.large` Convertible Reserved Instance. To change it to a smaller `t2.medium` instance and a `m3.medium` instance:

1. Modify the `t2.large` Convertible Reserved Instance by splitting it into two `t2.medium` Convertible Reserved Instances. A single `t2.large` instance has the same instance size footprint as two `t2.medium` instances.
2. Exchange one of the new `t2.medium` Convertible Reserved Instances for an `m3.medium` Convertible Reserved Instance.

For more information, see [Support for modifying instance sizes \(p. 428\)](#) and [Submit exchange requests \(p. 437\)](#).

Submit exchange requests

You can exchange your Convertible Reserved Instances using the Amazon EC2 console or a command line tool.

Exchange a Convertible Reserved Instance using the console

You can search for Convertible Reserved Instances offerings and select your new configuration from the choices provided.

New console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find offering**.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose **Review**.
6. Choose **Exchange**, and then **Close**.

Old console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find Offering**.
4. Select a new Convertible Reserved Instance. The **Instance Count** column displays the number of Reserved Instances that you receive for the exchange. When you have selected a Convertible Reserved Instance that meets your needs, choose **Exchange**.

The Reserved Instances that were exchanged are retired, and the new Reserved Instances are displayed in the Amazon EC2 console. This process can take a few minutes to propagate.

Exchange a Convertible Reserved Instance using the command line interface

To exchange a Convertible Reserved Instance, first find a new Convertible Reserved Instance that meets your needs:

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (Tools for Windows PowerShell)

Get a quote for the exchange, which includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:

- [get-reserved-instances-exchange-quote](#) (AWS CLI)
- [GetEC2ReservedInstancesExchangeQuote](#) (Tools for Windows PowerShell)

Finally, perform the exchange:

- [accept-reserved-instances-exchange-quote \(AWS CLI\)](#)
- [Confirm-EC2ReservedInstancesExchangeQuote \(Tools for Windows PowerShell\)](#)

Reserved Instance quotas

There is a limit to the number of Reserved Instances that you can purchase per month, as follows:

- For each Region, you can purchase 20 [regional \(p. 400\)](#) Reserved Instances per month.
- Plus, for each Availability Zone, you can purchase an additional 20 [zonal \(p. 400\)](#) Reserved Instances per month.

For example, in a Region with three Availability Zones, the limit is 80 Reserved Instances per month: 20 regional Reserved Instances for the Region plus 20 zonal Reserved Instances for each of the three Availability Zones ($20 \times 3 = 60$).

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional Reserved Instances, you will not be able to launch more instances because you have reached your On-Demand Instance limit.

Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches or exceeds the number of regional Reserved Instances you intend to own. If required, make sure you request an increase to your On-Demand Instance limit *before* purchasing more regional Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone—provides capacity reservation as well as a discount. You *can exceed* your running On-Demand Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20 On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a total of 40 running instances.

The Amazon EC2 console provides quota information. For more information, see [View your current limits \(p. 1706\)](#).

Scheduled Reserved Instances

With Scheduled Reserved Instances, you can reserve capacity that is scheduled to recur daily, weekly, or monthly, with a specified start time and duration, for a one-year term. After you complete your purchase, the instances are available to launch during the time windows that you specified.

Important

You cannot purchase Scheduled Reserved Instances at this time. AWS does not have any capacity available for Scheduled Reserved Instances or any plans to make it available in the future. To reserve capacity, use [On-Demand Capacity Reservations \(p. 538\)](#) instead. For discounted rates, use [Savings Plans](#).

Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available and the maximum price per hour for your request exceeds the Spot price.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see [Amazon EC2 Spot Instances](#).

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- **Spot capacity pool** – A set of unused EC2 instances with the same instance type (for example, `m5.large`) and Availability Zone.
- **Spot price** – The current price of a Spot Instance per hour.
- **Spot Instance request** – Requests a Spot Instance. The request provides the maximum price per hour that you are willing to pay for a Spot Instance. If you don't specify a maximum price, the default maximum price is the On-Demand price. When the maximum price per hour for your request exceeds the Spot price, Amazon EC2 fulfills your request if capacity is available. A Spot Instance request is either *one-time* or *persistent*. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is terminated.
- **EC2 instance rebalance recommendation** – Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption. This signal gives you the opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.
- **Spot Instance interruption** – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back or the Spot price exceeds the maximum price for your request. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

Key differences between Spot Instances and On-Demand Instances

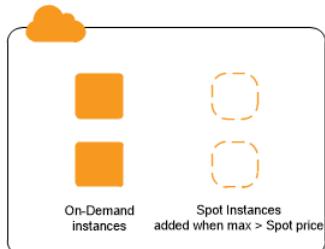

The following table lists the key differences between Spot Instances and On-Demand Instances.

	Spot Instances	On-Demand Instances
Launch time	Can only be launched immediately if the Spot Instance request is active and capacity is available.	Can only be launched immediately if you make a manual launch request and capacity is available.

	Spot Instances	On-Demand Instances
Available capacity	If capacity is not available, the Spot Instance request continues to automatically make the launch request until capacity becomes available.	If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).
Hourly price	The hourly price for Spot Instances varies based on demand.	The hourly price for On-Demand Instances is static.
Rebalance recommendation	The signal that Amazon EC2 emits for a recommendation running Spot Instance when the instance is at an elevated risk of interruption.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).
Instance interruption	You can stop and start an Amazon EBS-backed Spot Instance. In addition, the Amazon EC2 Spot service can interrupt (p. 475) an individual Spot Instance if capacity is no longer available, the Spot price exceeds your maximum price, or demand for Spot Instances increases.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).

Strategies for using Spot Instances

One strategy is to maintain a minimum level of guaranteed compute resources for your applications by launching a core group of On-Demand Instances, and supplementing them with Spot Instances when the opportunity arises.

Related services

You can provision Spot Instances directly using Amazon EC2. You can also provision Spot Instances using other services in AWS. For more information, see the following documentation.

Amazon EC2 Auto Scaling and Spot Instances

You can create launch templates or configurations with the maximum price that you are willing to pay, so that Amazon EC2 Auto Scaling can launch Spot Instances. For more information, see [Requesting Spot Instances for fault-tolerant and flexible applications](#) and [Auto Scaling groups with multiple instance types and purchase options](#) in the *Amazon EC2 Auto Scaling User Guide*.

Amazon EMR and Spot Instances

There are scenarios where it can be useful to run Spot Instances in an Amazon EMR cluster. For more information, see [Spot Instances](#) and [When Should You Use Spot Instances](#) in the *Amazon EMR Management Guide*.

AWS CloudFormation templates

AWS CloudFormation enables you to create and manage a collection of AWS resources using a template in JSON format. AWS CloudFormation templates can include the maximum price you are willing to pay. For more information, see [EC2 Spot Instance Updates - Auto Scaling and CloudFormation Integration](#).

AWS SDK for Java

You can use the Java programming language to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#) and [Tutorial: Advanced Amazon EC2 Spot Request Management](#).

AWS SDK for .NET

You can use the .NET programming environment to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#).

Pricing and savings

You pay the Spot price for Spot Instances, which is set by Amazon EC2 and adjusted gradually based on the long-term supply of and demand for Spot Instances. If the maximum price for your request exceeds the current Spot price, Amazon EC2 fulfills your request if capacity is available. Your Spot Instances run until you terminate them, capacity is no longer available, the Spot price exceeds your maximum price, or your Amazon EC2 Auto Scaling group terminates them during [scale in](#).

If you or Amazon EC2 interrupts a running Spot Instance, you are charged for the seconds used or the full hour, or you receive no charge, depending on the operating system used and who interrupted the Spot Instance. For more information, see [Billing for interrupted Spot Instances \(p. 484\)](#).

View prices

To view the current (updated every five minutes) lowest Spot price per AWS Region and instance type, see the [Amazon EC2 Spot Instances Pricing](#) page.

To view the Spot price history for the past three months, use the Amazon EC2 console or the [describe-spot-price-history](#) command (AWS CLI). For more information, see [Spot Instance pricing history \(p. 446\)](#).

We independently map Availability Zones to codes for each AWS account. Therefore, you can get different results for the same Availability Zone code (for example, `us-west-2a`) between different accounts.

View savings

You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. You can view the savings made in the last hour or the last three days, and you can view the average cost per vCPU hour and per memory (GiB) hour. Savings are estimated and may differ from actual savings because they do not include the billing adjustments for your usage. Best practices for EC2 Spot

Amazon EC2 Spot Instances are spare EC2 compute capacity in the AWS Cloud that are available to you at savings of up to 90% off compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notification, when Amazon EC2 needs the capacity back.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn't a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. It's also not recommended for workloads that are intolerant of occasional periods when the target capacity is not completely available. We strongly warn against using Spot Instances for these workloads or attempting to fail-over to On-Demand Instances to handle interruptions.

Regardless of whether you're an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

Spot best practices

- [Prepare individual instances for interruptions \(p. 443\)](#)
- [Be flexible about instance types and Availability Zones \(p. 443\)](#)
- [Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity \(p. 443\)](#)
- [Use the capacity optimized allocation strategy \(p. 443\)](#)
- [Use proactive capacity rebalancing \(p. 444\)](#)
- [Use integrated AWS services to manage your Spot Instances \(p. 444\)](#)

Prepare individual instances for interruptions

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a new signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this new signal by using the Capacity Rebalancing feature in Auto Scaling groups and Spot Fleet. For more information, see [Use proactive capacity rebalancing \(p. 444\)](#).

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in [Amazon EventBridge](#) that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see [Monitor rebalance recommendation signals \(p. 473\)](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

For more information, see [EC2 instance rebalance recommendations \(p. 472\)](#) and [Spot Instance interruptions \(p. 475\)](#).

Be flexible about instance types and Availability Zones

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone (for example, us-east-1a). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for c5.large if you'd be willing to use larges from the c4, m5, and m4 families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and Spot Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or a Spot Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide* and [Create a Spot Fleet request \(p. 872\)](#) in this user guide.

Use the capacity optimized allocation strategy

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the capacity

optimized strategy because this strategy automatically provisions instances from the most-available Spot capacity pools. You can also take advantage of the capacity optimized allocation strategy in Spot Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information about allocation strategies, see [Spot Instances](#) in the *Amazon EC2 Auto Scaling User Guide* and [Configure Spot Fleet for capacity optimization \(p. 842\)](#) in this user guide.

Use proactive capacity rebalancing

Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running Spot Instance receives the two-minute Spot Instance interruption notice. When Capacity Rebalancing is enabled, Auto Scaling or Spot Fleet attempts to proactively replace Spot Instances that have received a rebalance recommendation, providing the opportunity to rebalance your workload to new Spot Instances that are not at elevated risk of interruption.

Capacity Rebalancing complements the capacity optimized allocation strategy (which is designed to help find the most optimal spare capacity) and the mixed instances policy (which is designed to enhance availability by deploying instances across multiple instance types running in multiple Availability Zones).

For more information, see [Capacity Rebalancing \(p. 861\)](#).

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon ECS, AWS Batch, Amazon EKS, SageMaker, AWS Elastic Beanstalk, and Amazon GameLift. To learn more about Spot best practices with these services, see the [Amazon EC2 Spot Instances Workshops Website](#).

How Spot Instances work

To launch a Spot Instance, either you create a *Spot Instance request*, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see [Getting Started with Amazon EC2 Spot Instances](#). In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request. For more information, see [Create a Spot Instance request \(p. 452\)](#).
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see [Create an EC2 Fleet \(p. 828\)](#).
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see [Create a Spot Fleet request \(p. 872\)](#).

The Spot Instance request must include the maximum price that you're willing to pay per hour per instance. If you don't specify a price, the price defaults to the On-Demand price. The request can include other constraints such as the instance type and Availability Zone.

Your Spot Instance launches if the maximum price that you're willing to pay exceeds the Spot price, and if there is available capacity. If the maximum price you're willing to pay is lower than the Spot price, then your instance does not launch. However, because Amazon EC2 gradually adjusts the Spot price based on the long-term supply of and demand for Spot Instances, the maximum price you're willing to pay might eventually exceed the Spot price, in which case your instance will launch.

Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a *Spot Instance interruption*).

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises, when the supply of Spot Instances decreases, or when the Spot price exceeds your maximum price. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see [Spot Instance interruptions \(p. 475\)](#).

You can stop, start, reboot, or terminate an Amazon EBS-backed Spot Instance. The Spot service can stop, terminate, or hibernate a Spot Instance when it interrupts it.

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group (for example, if the Spot price exceeds your maximum price), it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell the Spot service to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC

Amazon EC2 uses the Availability Zone for the specified subnet.

Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- You should use the default maximum price (the On-Demand price), or base your maximum price on the Spot price history of Spot Instances in a VPC.
- [Default VPC] If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot Instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When you request Spot Instances, we recommend that you use the default maximum price (the On-Demand price). When your request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. If you want to specify a maximum price, we recommend that you first review the Spot price history. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

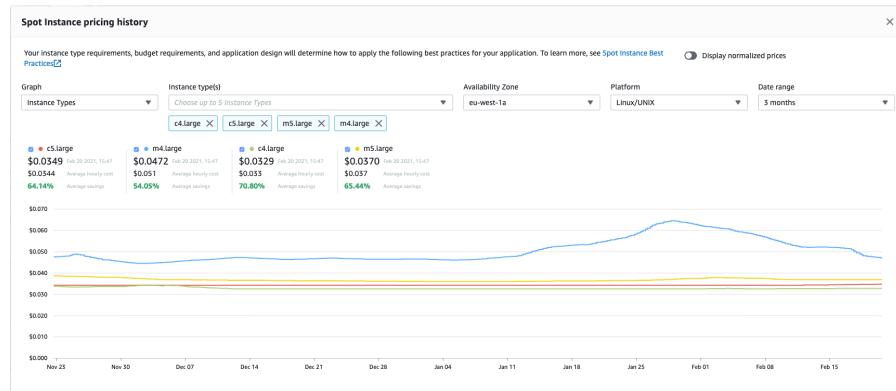

To view the current Spot prices

For the *current* Spot Instance prices, see [Amazon EC2 Spot Instances Pricing](#).

To view the Spot price history (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Pricing history**.
4. For **Graph**, choose to compare the price history by **Availability Zones** or by **Instance Types**.
 - If you choose **Availability Zones**, then choose the **Instance type**, operating system (**Platform**), and **Date range** for which to view the price history.
 - If you choose **Instance Types**, then choose up to five **Instance type(s)**, the **Availability Zone**, operating system (**Platform**), and **Date range** for which to view the price history.

The following screenshot shows a price comparison for different instance types.

5. Move your pointer over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.
6. To display the price per vCPU, toggle on **Display normalized prices**. To display the price for the instance type, toggle off **Display normalized prices**.

To view the Spot price history using the command line

You can use one of the following commands. For more information, see [Access Amazon EC2 \(p. 3\)](#).

- [describe-spot-price-history](#) (AWS CLI)
- [Get-EC2SpotPriceHistory](#) (AWS Tools for Windows PowerShell)

Savings from purchasing Spot Instances

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the **Savings** section shows the Spot usage and savings information for a Spot Fleet.

Spot usage and savings					
4 Spot Instances	266 vCPU-hours	700 Mem(GiB)-hours	\$9.55 On-Demand total	\$2.99 Spot total	69% Savings
				\$0.0112 Average cost per vCPU-hour	\$0.0043 Average cost per mem(GiB)-hour
Details					
t3.medium (1)	2 vCPU hours	4 mem(GiB)-hours	\$0.01 total	70% savings	
m4.large (1)	144 vCPU hours	576 mem(GiB)-hours	\$2.52 total	68% savings	
t2.micro (2)	120 vCPU hours	120 mem(GiB)-hours	\$0.46 total	70% savings	

You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per vCPU-hour = Spot total / vCPU-hours**.

- **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per mem(GiB)-hour = Spot total / Mem(GiB)-hours.**
- **Details table** – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

To view the savings information for a Spot Fleet (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.

Alternatively, select the check box next to the Spot Fleet request ID and choose the **Savings** tab.
4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

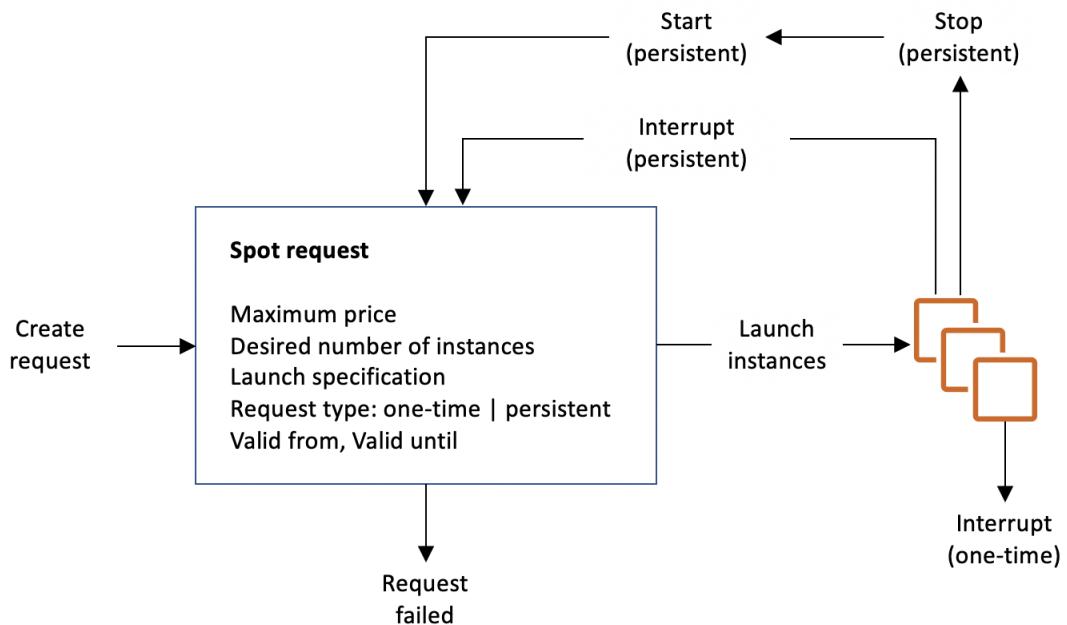

To view the savings information for all running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

Spot Instance requests

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, the Availability Zone, and the maximum price that you are willing to pay per instance hour. If your maximum price exceeds the current Spot price, Amazon EC2 fulfills your request immediately if capacity is available. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.

Spot Instance request states

A Spot Instance request can be in one of the following states:

- **open** – The request is waiting to be fulfilled.
- **active** – The request is fulfilled and has an associated Spot Instance.
- **failed** – The request has one or more bad parameters.
- **closed** – The Spot Instance was interrupted or terminated.
- **disabled** – You stopped the Spot Instance.
- **cancelled** – You canceled the request, or the request expired.

The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).

A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If the Spot price exceeds your maximum price or capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.

A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If the Spot price exceeds your maximum price or capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when your maximum price exceeds the Spot price or capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available and your maximum price exceeds the current Spot price. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see [Stop a Spot Instance \(p. 461\)](#), [Start a Spot Instance \(p. 462\)](#), and [Terminate a Spot Instance \(p. 463\)](#).

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see [Spot request status \(p. 466\)](#).

Define a duration for your Spot Instances

Spot Instances with a defined duration (also known as Spot blocks) are no longer available to new customers from July 1, 2021. For customers who have previously used the feature, we will continue to support Spot Instances with a defined duration until December 31, 2022.

Specify a tenancy for your Spot Instances

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see [Dedicated Instances \(p. 531\)](#) and the [Amazon EC2 Dedicated Instances](#) product page.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of dedicated when you create the Spot Instance request. For more information, see [Create a Spot Instance request \(p. 452\)](#).

- Request a Spot Instance in a VPC with an instance tenancy of dedicated. For more information, see [Create a VPC with an instance tenancy of dedicated \(p. 534\)](#). You cannot request a Spot Instance with a tenancy of default if you request it in a VPC with an instance tenancy of dedicated.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see [Using Service-Linked Roles](#) in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf.

Permissions granted by **AWSServiceRoleForEC2Spot**

Amazon EC2 uses **AWSServiceRoleForEC2Spot** to complete the following actions:

- **ec2:DescribeInstances** – Describe Spot Instances
- **ec2:StopInstances** – Stop Spot Instances
- **ec2:StartInstances** – Start Spot Instances

Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2Spot** service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2Spot** role in your AWS account. For more information, see [A New Role Appeared in My Account](#) in the *IAM User Guide*.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

To create **AWSServiceRoleForEC2Spot** using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select type of trusted entity** page, choose **EC2, EC2 - Spot Instances, Next: Permissions**.
5. On the next page, choose **Next:Review**.
6. On the **Review** page, choose **Create role**.

To create **AWSServiceRoleForEC2Spot** using the AWS CLI

Use the `create-service-linked-role` command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```

If you no longer need to use Spot Instances, we recommend that you delete the **AWSServiceRoleForEC2Spot** role. After this role is deleted from your account, Amazon EC2 will create the role again if you request Spot Instances.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an [encrypted AMI \(p. 203\)](#) or an [encrypted Amazon EBS snapshot \(p. 1542\)](#) for your Spot Instances and you use a customer managed key for encryption, you must grant the **AWSServiceRoleForEC2Spot** role permission to use the customer managed key so that Amazon EC2 can launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using Grants](#) and [Using Key Policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

To grant the AWSServiceRoleForEC2Spot role permissions to use the customer managed key

- Use the [create-grant](#) command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Spot** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the `key-id` parameter and the ARN of the customer managed key. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2Spot** service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-
    east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Spot \
    --operations "Decrypt" "Encrypt" "GenerateDataKey"
    "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
    "ReEncryptTo"
```

Create a Spot Instance request

The procedure for requesting a Spot Instance is similar to the procedure for launching an On-Demand Instance. You can request a Spot Instance in the following ways:

- To request a Spot Instance using the console, use the launch instance wizard. For more information, see [To create a Spot Instance request \(console\) \(p. 453\)](#).
- To request a Spot Instance using the CLI, use the [request-spot-instances](#) command or the [run-instances](#) command. For more information, see [To create a Spot Instance request using request-spot-instances \(CLI\)](#) and [To create a Spot Instance request using run-instances \(CLI\)](#).

After you've submitted your Spot Instance request, you can't change the parameters of the request. This means that you can't make changes to the maximum price that you're willing to pay.

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests so that you can track the status of each request separately. For more information about tracking Spot Instance requests, see [Spot request status \(p. 466\)](#).

To launch a fleet that includes Spot Instances and On-Demand Instances, see [Create a Spot Fleet request \(p. 872\)](#).

Note

You can't launch a Spot Instance and an On-Demand Instance in the same call using the launch instance wizard or the [run-instances](#) command.

Prerequisites

Before you begin, decide on your maximum price, how many Spot Instances you'd like, and what instance type to use. To review Spot price trends, see [Spot Instance pricing history \(p. 446\)](#).

To create a Spot Instance request (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch Instance**.
4. On the **Choose an Amazon Machine Image (AMI)** page, choose an AMI. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 581\)](#).
5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch, and then choose **Next: Configure Instance Details**. For more information, see [Step 2: Choose an Instance Type \(p. 582\)](#).
6. On the **Configure Instance Details** page, configure the Spot Instance request as follows:

- **Number of instances:** Enter the number of instances to launch.

Note

Amazon EC2 creates a separate request for each Spot Instance.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. When you choose this option, the following fields appear.
- **Current price:** The current Spot price in each Availability Zone is displayed for the instance type that you selected.
- (Optional) **Maximum price:** You can leave the field empty, or you can specify the maximum amount you're willing to pay.
 - If you leave the field empty, then the maximum price defaults to the current On-Demand price. Your Spot Instance launches at the current Spot price, not exceeding the On-Demand price.
 - If you specify a maximum price that is more than the current Spot Price, your Spot Instance launches and is charged at the current Spot price.
 - If you specify a maximum price that is lower than the Spot price, your Spot Instance is not launched.
- **Persistent request:** Choose **Persistent request** to resubmit the Spot Instance request if your Spot Instance is interrupted.
- **Interruption behavior:** By default, the Spot service terminates a Spot Instance when it is interrupted. If you choose **Persistent request**, you can then specify that the Spot service stops or hibernates your Spot Instance when it's interrupted. For more information, see [Interruption behavior \(p. 476\)](#).
- (Optional) **Request valid to:** Choose **Edit** to specify when the Spot Instance request expires.

For more information about configuring your Spot Instance, see [Step 3: Configure Instance Details \(p. 582\)](#).

7. The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. For more information, see [Step 4: Add Storage \(p. 585\)](#).
8. On the **Add Tags** page, specify [tags \(p. 1692\)](#) by providing key and value combinations. For more information, see [Step 5: Add Tags \(p. 585\)](#).
9. On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other

traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).) Select or create a security group, and then choose **Review and Launch**. For more information, see [Step 6: Configure Security Group \(p. 585\)](#).

10. On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link. When you are ready, choose **Launch**. For more information, see [Step 7: Review Instance Launch and Select Key Pair \(p. 586\)](#).
11. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair that you created when getting set up. For more information, see [Amazon EC2 key pairs and Linux instances \(p. 1310\)](#).

Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

12. To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see [Troubleshoot instance launch issues \(p. 1709\)](#).

To create a Spot Instance request using `request-spot-instances` (AWS CLI)

Use the `request-spot-instances` command to create a one-time request.

```
aws ec2 request-spot-instances \
--instance-count 5 \
--type "one-time" \
--launch-specification file://specification.json
```

Use the `request-spot-instances` command to create a persistent request.

```
aws ec2 request-spot-instances \
--instance-count 5 \
--type "persistent" \
--launch-specification file://specification.json
```

For example launch specification files to use with these commands, see [Spot Instance request example launch specifications \(p. 464\)](#). If you download a launch specification file from the console, you must use the `request-spot-fleet` command instead (the console specifies a Spot Instance request using a Spot Fleet).

To create a Spot Instance request using `run-instances` (AWS CLI)

Use the `run-instances` command and specify the Spot Instance options in the `--instance-market-options` parameter.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type t2.micro \
--count 5 \
--subnet-id subnet-08fc749671b2d077c \
--key-name MyKeyPair \
--security-group-ids sg-0b0384b66d7d692f9 \
--instance-market-options file://spot-options.json
```

The following is the data structure to specify in the JSON file for `--instance-market-options`. You can also specify `ValidUntil` and `InstanceInterruptionBehavior`. If you do not specify a field in the data structure, the default value is used. This example creates a one-time request and specifies `0.02` as the maximum price you're willing to pay for the Spot Instance.

```
{  
    "MarketType": "spot",  
    "SpotOptions": {  
        "MaxPrice": "0.02",  
        "SpotInstanceType": "one-time"  
    }  
}
```

Find running Spot Instances

Amazon EC2 launches a Spot Instance when the maximum price exceeds the Spot price and capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself. If your maximum price is exactly equal to the Spot price, there is a chance that your Spot Instance remains running, depending on demand.

To find running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**. You can see both Spot Instance requests and Spot Fleet requests. If a Spot Instance request has been fulfilled, **Capacity** is the ID of the Spot Instance. For a Spot Fleet, **Capacity** indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose **Instances**.

Note

For Spot Instance requests that are created by a Spot Fleet, the requests are not tagged instantly with the system tag that indicates the Spot Fleet to which they belong, and for a period of time may appear separate from Spot Fleet request.

Alternatively, in the navigation pane, choose **Instances**. In the top right corner, choose the settings icon () , and then under **Attribute columns**, select **Instance lifecycle**. For each instance, **Instance lifecycle** is either normal, spot, or scheduled.

To find running Spot Instances (AWS CLI)

To enumerate your Spot Instances, use the `describe-spot-instance-requests` command with the `--query` option.

```
aws ec2 describe-spot-instance-requests \  
  --query "SpotInstanceRequests[*].{ID:InstanceId}"
```

The following is example output:

```
[  
    {  
        "ID": "i-1234567890abcdef0"  
    },  
    {  
        "ID": "i-0598c7d356eba48d7"  
    }  
]
```

Alternatively, you can enumerate your Spot Instances using the `describe-instances` command with the `--filters` option.

```
aws ec2 describe-instances \  
  --filters "Name=instance-lifecycle,Values=spot"
```

To describe a single Spot Instance instance, use the [describe-spot-instance-requests](#) command with the `--spot-instance-request-ids` option.

```
aws ec2 describe-spot-instance-requests \
--spot-instance-request-ids sir-08b93456
```

Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see [Tag your Amazon EC2 resources \(p. 1692\)](#).

Contents

- [Prerequisites \(p. 456\)](#)
- [Tag a new Spot Instance request \(p. 458\)](#)
- [Tag an existing Spot Instance request \(p. 458\)](#)
- [View Spot Instance request tags \(p. 459\)](#)

Prerequisites

Grant the IAM user the permission to tag resources. For more information about IAM policies and example policies, see [Example: Tag resources \(p. 1280\)](#).

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

- If you use the launch instance wizard or `run-instances` to request Spot Instances, see [To grant an IAM user the permission to tag resources when using the launch instance wizard or run-instances](#).
- If you use the `request-spot-instances` command to request Spot Instances, see [To grant an IAM user the permission to tag resources when using request-spot-instances](#).

To grant an IAM user the permission to tag resources when using the launch instance wizard or run-instances

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the IAM user permission to launch an instance.
- For `Resource`, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- For `Resource`, specify `*`. This allows users to tag all resources that are created during instance launch.

Note

When you use the RunInstances action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or include a * wildcard in the CreateTags allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see [Work with Spot Instances \(p. 1275\)](#).

To grant an IAM user the permission to tag resources when using request-spot-instances

Create a IAM policy that includes the following:

- The `ec2:RequestSpotInstances` action. This grants the IAM user permission to create a Spot Instance request.
- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- For `Resource`, specify `spot-instances-request`. This allows users to tag only the Spot Instance request.

Tag a new Spot Instance request

To tag a new Spot Instance request using the console

1. Follow the [Create a Spot Instance request \(p. 452\)](#) procedure.
2. To add a tag, on the **Add Tags** page, choose **Add Tag**, and enter the key and value for the tag. Choose **Add another tag** for each additional tag.

For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that **Instances**, **Volumes**, and **Spot Instance Requests** are selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.
3. Complete the required fields to create a Spot Instance request, and then choose **Launch**. For more information, see [Create a Spot Instance request \(p. 452\)](#).

To tag a new Spot Instance request using the AWS CLI

To tag a Spot Instance request when you create it, configure the Spot Instance request configuration as follows:

- Specify the tags for the Spot Instance request using the `--tag-specification` parameter.
- For `ResourceType`, specify `spot-instances-request`. If you specify another value, the Spot Instance request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Instance request is tagged with two tags: `Key=Environment` and `Value=Production`, and `Key=Cost-Center` and `Value=123`.

```
aws ec2 request-spot-instances \  
  --instance-count 5 \  
  --type "one-time" \  
  --launch-specification file://specification.json \  
  --tag-specification 'ResourceType=spot-instances-  
request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]'
```

Tag an existing Spot Instance request

To tag an existing Spot Instance request using the console

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

1. Open the Spot console at <https://console.aws.amazon.com/ec2spot>.

2. Select your Spot Instance request.
3. Choose the **Tags** tab and choose **Create Tag**.

To tag an existing Spot Instance using the console

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see [Add and delete tags on an individual resource \(p. 1699\)](#).

To tag an existing Spot Instance request or Spot Instance using the AWS CLI

Use the [create-tags](#) command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with Key=purpose and Value=test.

```
aws ec2 create-tags \
--resources sir-08b93456 i-1234567890abcdef0 \
--tags Key=purpose,Value=test
```

View Spot Instance request tags

To view Spot Instance request tags using the console

1. Open the Spot console at <https://console.aws.amazon.com/ec2spot>.
2. Select your Spot Instance request and choose the **Tags** tab.

To describe Spot Instance request tags

Use the [describe-tags](#) command to view the tags for the specified resource. In the following example, you describe the tags for the specified request.

```
aws ec2 describe-tags \
--filters "Name=resource-id,Values=sir-11112222-3333-4444-5555-66666EXAMPLE"
```

```
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-instances-request",
      "Value": "Production"
    },
    {
      "Key": "Another key",
      "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-instances-request",
      "Value": "Another value"
    }
  ]
}
```

You can also view the tags of a Spot Instance request by describing the Spot Instance request.

Use the [describe-spot-instance-requests](#) command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```
aws ec2 describe-spot-instance-requests \
```

```
--spot-instance-request-ids sir-11112222-3333-4444-5555-66666EXAMPLE

Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are open, active, or disabled.

- Your Spot Instance request is **open** when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is **active** when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is **disabled** when you stop your Spot Instance.

If your Spot Instance request is **active** and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see [Terminate a Spot Instance \(p. 463\)](#).

To cancel a Spot Instance request (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests** and select the Spot Instance request.
3. Choose **Actions, Cancel request**.
4. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the **Cancel Spot request** dialog box, select **Terminate instances**, and then choose **Confirm**.

To cancel a Spot Instance request (AWS CLI)

- Use the `cancel-spot-instance-requests` command to cancel the specified Spot Instance request.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-ids sir-08b93456
```

Stop a Spot Instance

If you don't need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

Note

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.

We don't charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

- You can only stop a Spot Instance if the Spot Instance was launched from a persistent Spot Instance request.
- You can't stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.
- You can't stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.

New console

To stop a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Stop instance**.
4. When prompted for confirmation, choose **Stop**.

Old console

To stop a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Actions, Instance State, Stop**.

AWS CLI

To stop a Spot Instance (AWS CLI)

- Use the [stop-instances](#) command to manually stop one or more Spot Instances.

```
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

Start a Spot Instance

You can start a Spot Instance that you previously stopped. The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

Prerequisites

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.
- The Spot price is lower than your maximum price.

Limitations

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

New console

To start a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Start instance**.

Old console

To start a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Actions, Instance State, Start**.

AWS CLI

To start a Spot Instance (AWS CLI)

- Use the `start-instances` command to manually start one or more Spot Instances.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

Terminate a Spot Instance

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the `open` state so that a new Spot Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an active Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a disabled Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For information about canceling a Spot Instance request, see [Cancel a Spot Instance request \(p. 461\)](#).

New console

To manually terminate a Spot Instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that `spot` appears in the **Instance lifecycle** column.
5. Select the instance, and choose **Actions, Instance state, Terminate instance**.
6. Choose **Terminate** when prompted for confirmation.

Old console

To manually terminate a Spot Instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you

need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that **spot** appears in the **Lifecycle** column.
5. Select the instance, and choose **Actions, Instance State, Terminate**.
6. Choose **Yes, Terminate** when prompted for confirmation.

AWS CLI

To manually terminate a Spot Instance using the AWS CLI

- Use the [terminate-instances](#) command to manually terminate Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7
```

Spot Instance request example launch specifications

The following examples show launch configurations that you can use with the [request-spot-instances](#) command to create a Spot Instance request. For more information, see [Create a Spot Instance request \(p. 452\)](#).

1. [Launch Spot Instances \(p. 464\)](#)
2. [Launch Spot Instances in the specified Availability Zone \(p. 464\)](#)
3. [Launch Spot Instances in the specified subnet \(p. 465\)](#)
4. [Launch a Dedicated Spot Instance \(p. 465\)](#)

Example 1: Launch Spot Instances

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```
{  
    "ImageId": "ami-1a2b3c4d",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],  
    "InstanceType": "m3.medium",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 2: Launch Spot Instances in the specified Availability Zone

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```
{  
    "ImageId": "ami-1a2b3c4d",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],  
    "Placement": {  
        "AvailabilityZone": "us-west-2a"  
    }  
}
```

```
{  
    "InstanceType": "m3.medium",  
    "Placement": {  
        "AvailabilityZone": "us-west-2a"  
    },  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```
{  
    "ImageId": "ami-1a2b3c4d",  
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],  
    "InstanceType": "m3.medium",  
    "SubnetId": "subnet-1a2b3c4d",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in example 3.

```
{  
    "ImageId": "ami-1a2b3c4d",  
    "KeyName": "my-key-pair",  
    "InstanceType": "m3.medium",  
    "NetworkInterfaces": [  
        {  
            "DeviceIndex": 0,  
            "SubnetId": "subnet-1a2b3c4d",  
            "Groups": [ "sg-1a2b3c4d" ],  
            "AssociatePublicIpAddress": true  
        }  
    ],  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of dedicated. A Dedicated Spot Instance must be launched in a VPC.

```
{  
    "ImageId": "ami-1a2b3c4d",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d" ],  
    "InstanceType": "c3.8xlarge",  
    "SubnetId": "subnet-1a2b3c4d",  
    "Placement": {  
        "Tenancy": "dedicated"  
    }  
}
```

}

Spot request status

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn't fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

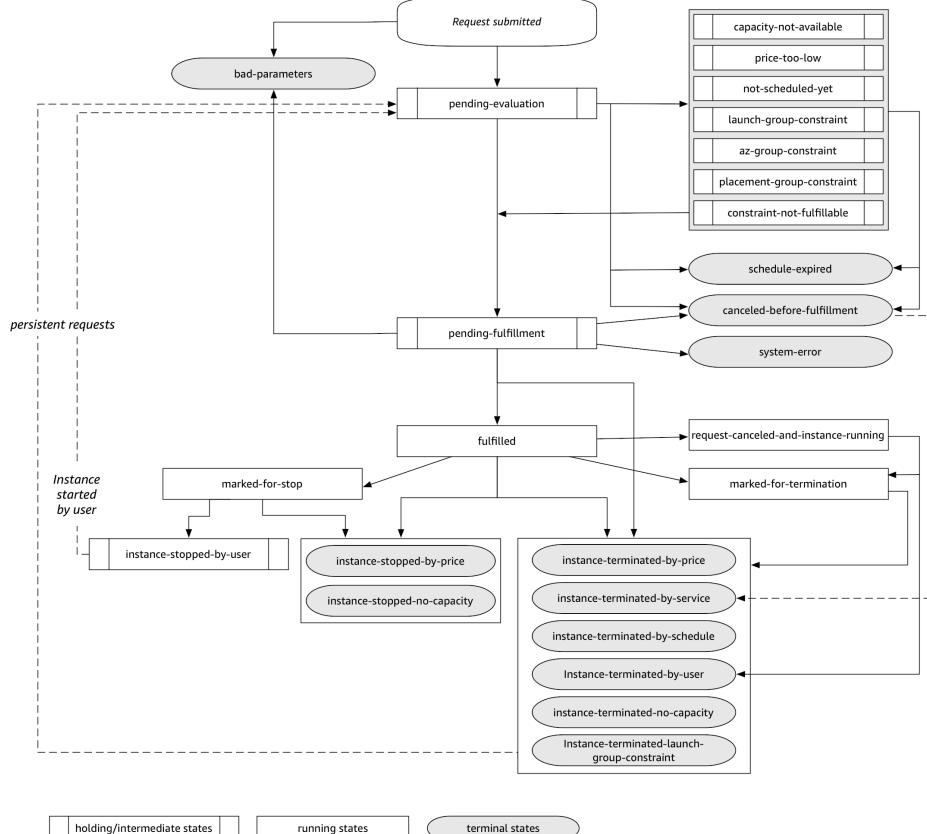

At each step of the process—also called the Spot request *lifecycle*—specific events determine successive request states.

Contents

- [Lifecycle of a Spot request \(p. 466\)](#)
- [Get request status information \(p. 469\)](#)
- [Spot request status codes \(p. 470\)](#)

Lifecycle of a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.

Pending evaluation

As soon as you create a Spot Instance request, it goes into the pending-evaluation state unless one or more request parameters are not valid (`bad-parameters`).

Status code	Request state	Instance state
pending-evaluation	open	n/a
bad-parameters	closed	n/a

Holding

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if you specify a maximum price below the current Spot price, your request stays in a holding state until the Spot price goes below your maximum price. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

Status code	Request state	Instance state
capacity-not-available	open	n/a
price-too-low	open	n/a
not-scheduled-yet	open	n/a
launch-group-constraint	open	n/a
az-group-constraint	open	n/a
placement-group-constraint	open	n/a
constraint-not-fulfillable	open	n/a

Pending evaluation/fulfillment-terminal

Your Spot Instance request can go to a terminal state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

Status code	Request state	Instance state
schedule-expired	cancelled	n/a
canceled-before-fulfillment*	cancelled	n/a
bad-parameters	failed	n/a
system-error	closed	n/a

* If you cancel the request.

Pending fulfillment

When the constraints you specified (if any) are met and your maximum price is equal to or higher than the current Spot price, your Spot request goes into the pending-fulfillment state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

Status code	Request state	Instance state
pending-fulfillment	open	n/a

Fulfilled

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

Status code	Request state	Instance state
fulfilled	active	pending → running
fulfilled	active	stopped → running

If you stop a Spot Instance, your Spot request goes into the `marked-for-stop` or `instance-stopped-by-user` state until the Spot Instance can be started again or the request is cancelled.

Status code	Request state	Instance state
marked-for-stop	active	stopping
instance-stopped-by-user*	disabled or cancelled**	stopped

* A Spot Instance goes into the `instance-stopped-by-user` state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the pending-evaluation state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

** The Spot request state is disabled if you stop the Spot Instance but do not cancel the request. The request state is cancelled if your Spot Instance is stopped and the request expires.

Fulfilled-terminal

Your Spot Instances continue to run as long as your maximum price is at or above the Spot price, there is available capacity for your instance type, and you don't terminate the instance. If a change in the Spot price or available capacity requires Amazon EC2 to terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.

Status code	Request state	Instance state
request-canceled-and-instance-running	cancelled	running

Status code	Request state	Instance state
marked-for-stop	active	running
marked-for-termination	active	running
instance-stopped-by-price	disabled	stopped
instance-stopped-by-user	disabled	stopped

instance-terminated-no-capacity	closed (one-time), open (persistent)	terminated
instance-terminated-launch-group-constraint	closed (one-time), open (persistent)	terminated

* The request state is **closed** if you terminate the instance but do not cancel the request. The request state is **cancelled** if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be **closed** or **cancelled**.

† When Amazon EC2 interrupts a Spot Instance if it needs the capacity back *and* the instance is configured to *terminate* on interruption, the status is immediately set to **instance-terminated-no-capacity** (it is not set to **marked-for-termination**). However, the instance remains in the **running** state for 2 minutes to reflect the 2-minute period when the instance receives the Spot Instance interruption notice. After 2 minutes, the instance state is set to **terminated**.

Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the pending-evaluation state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

Get request status information

You can get request status information using the AWS Management Console or a command line tool.

To get request status information (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Spot Requests** and select the Spot request.
3. To check the status, on the **Description** tab, check the **Status** field.

To get request status information using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [describe-spot-instance-requests](#) (AWS CLI)
- [Get-EC2SpotInstanceRequest](#) (AWS Tools for Windows PowerShell)

Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

az-group-constraint

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

bad-parameters

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.

canceled-before-fulfillment

The user canceled the Spot request before it was fulfilled.

capacity-not-available

There is not enough capacity available for the instances that you requested.

constraint-not-fulfillable

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

fulfilled

The Spot request is active, and Amazon EC2 is launching your Spot Instances.

instance-stopped-by-price

Your instance was stopped because the Spot price exceeded your maximum price.

instance-stopped-by-user

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

instance-stopped-no-capacity

Your instance was stopped due to EC2 capacity management needs.

instance-terminated-by-price

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

instance-terminated-by-schedule

Your Spot Instance was terminated at the end of its scheduled duration.

instance-terminated-by-service

Your instance was terminated from a stopped state.

instance-terminated-by-user or spot-instance-terminated-by-user

You terminated a Spot Instance that had been fulfilled, so the request state is `closed` (unless it's a persistent request) and the instance state is `terminated`.

instance-terminated-launch-group-constraint

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

instance-terminated-no-capacity

Your instance was terminated due to standard capacity management processes.

launch-group-constraint

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

limit-exceeded

The limit on the number of EBS volumes or total volume storage was exceeded. For more information about these limits and how to request an increase, see [Amazon EBS Limits](#) in the *Amazon Web Services General Reference*.

marked-for-stop

The Spot Instance is marked for stopping.

marked-for-termination

The Spot Instance is marked for termination.

not-scheduled-yet

The Spot request is not evaluated until the scheduled date.

pending-evaluation

After you make a Spot Instance request, it goes into the `pending-evaluation` state while the system evaluates the parameters of your request.

pending-fulfillment

Amazon EC2 is trying to provision your Spot Instances.

placement-group-constraint

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.

price-too-low

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains open.

request-canceled-and-instance-running

You canceled the Spot request while the Spot Instances are still running. The request is cancelled, but the instances remain running.

schedule-expired

The Spot request expired because it was not fulfilled before the specified date.

system-error

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 instance rebalance recommendations

An EC2 Instance *rebalance recommendation* is a signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the [two-minute Spot Instance interruption notice \(p. 481\)](#), giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.

Rebalance recommendations are made available as a CloudWatch event and as an item in the [instance metadata \(p. 726\)](#) on the Spot Instance. Events are emitted on a best effort basis.

Note

Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

Topics

- [Rebalance actions you can take \(p. 472\)](#)
- [Monitor rebalance recommendation signals \(p. 473\)](#)
- [Services that use the rebalance recommendation signal \(p. 475\)](#)

Rebalance actions you can take

These are some of the possible rebalancing actions that you can take:

Graceful shutdown

When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.

Prevent new work from being scheduled

When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances

You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see [Amazon EC2 Auto Scaling Capacity Rebalancing](#) in the *Amazon EC2 Auto Scaling User Guide*, and [Capacity Rebalancing \(p. 816\)](#) for EC2 Fleet and [Capacity Rebalancing \(p. 861\)](#) for Spot Fleet in this user guide.

Monitor rebalance recommendation signals

You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:

- [Use Amazon EventBridge \(p. 473\)](#)
- [Use instance metadata \(p. 474\)](#)

Use Amazon EventBridge

When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Instance Rebalance Recommendation",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],  
    "detail": {  
        "instance-id": "i-1234567890abcdef0"  
    }  
}
```

The following fields form the event pattern that is defined in the rule:

```
"detail-type": "EC2 Instance Rebalance Recommendation"
```

Identifies that the event is a rebalance recommendation event

```
source": "aws.ec2"
```

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an EC2 Instance Rebalance Recommendation event, which triggers the action defined by the rule.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. Choose **Create rule**.
3. Enter a **Name** for the rule, and, optionally, a description.

A rule can't have the same name as another rule in the same Region and on the same event bus.

4. For **Define pattern**, choose **Event pattern**.
5. Under **Event matching pattern**, choose **Custom pattern**.
6. In the **Event pattern** box, add the following pattern to match the EC2 Instance Rebalance Recommendation event, and then choose **Save**.

```
{  
    "source": [ "aws.ec2" ],  
    "detail-type": [ "EC2 Instance Rebalance Recommendation" ]  
}
```

7. For **Select event bus**, choose **AWS default event bus**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
8. Confirm that **Enable the rule on the selected event bus** is toggled on.
9. For **Target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
10. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person \(A2P\) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.
11. For **Configure input**, choose the input for the email, text message, or mobile push notification.
12. Choose **Create**.

For more information, see [Creating a rule for an AWS service](#) and [Event Patterns](#) in the *Amazon EventBridge User Guide*

Use instance metadata

The instance metadata category events/recommendations/rebalance provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \  
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, `events/recommendations/rebalance` is not present and you receive an HTTP 404 error when you try to retrieve it.

Services that use the rebalance recommendation signal

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- [Amazon EC2 Auto Scaling Capacity Rebalancing](#) in the *Amazon EC2 Auto Scaling User Guide*
- [Capacity Rebalancing \(p. 816\)](#) in the EC2 Fleet topic in this user guide
- [Capacity Rebalancing \(p. 861\)](#) in the Spot Fleet topic in this user guide

Spot Instance interruptions

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a *Spot Instance interruption*.

When Amazon EC2 interrupts a Spot Instance, it either terminates, stops, or hibernates the instance, depending on what you specified when you created the Spot request.

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted.

An On-Demand Instance specified in an EC2 Fleet or Spot Fleet cannot be interrupted.

- [Determine whether Amazon EC2 interrupted a Spot Instance \(p. 483\)](#)
- [Billing for interrupted Spot Instances \(p. 484\)](#)

Reasons for interruption

The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

Price

The Spot price is greater than your maximum price.

Capacity

Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.

Constraints

If your Spot request includes a constraint such as a launch group or an Availability Zone group, the Spot Instances are terminated as a group when the constraint can no longer be met.

You can see the historical interruption rates for your instance type in the [Spot Instance Advisor](#).

Interruption behavior

You can specify that Amazon EC2 must do one of the following when it interrupts a Spot Instance:

- [Stop interrupted Spot Instances \(p. 476\)](#)
- [Hibernate interrupted Spot Instances \(p. 477\)](#)
- [Terminate interrupted Spot Instances \(p. 480\)](#) (this is the default behavior)

Specify the interruption behavior

You can specify the interruption behavior when you create a Spot request. If you do not specify an interruption behavior, the default is that Amazon EC2 terminates Spot Instances when they are interrupted.

The way in which you specify the interruption behavior is different depending on how you request Spot Instances.

- If you request Spot Instances using the [launch instance wizard \(p. 580\)](#), you can specify the interruption behavior as follows: Select the **Persistent request** check box and then, from **Interruption behavior**, choose an interruption behavior.
- If you request Spot Instances using the [Spot console \(p. 872\)](#), you can specify the interruption behavior as follows: Select the **Maintain target capacity** check box and then, from **Interruption behavior**, choose an interruption behavior.
- If you configure Spot Instances in a [launch template \(p. 596\)](#), you can specify the interruption behavior as follows: In the launch template, expand **Advanced details** and select the **Request Spot Instances** check box. Choose **Customize** and then, from **Interruption behavior**, choose an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [create-fleet](#) CLI, you can specify the interruption behavior as follows: For `Instance INTERRUPTIONBehavior`, specify an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [request-spot-fleet](#) CLI, you can specify the interruption behavior as follows: For `Instance INTERRUPTIONBehavior`, specify an interruption behavior.
- If you configure Spot Instances using the [request-spot-instances](#) CLI, you can specify the interruption behavior as follows: For `--instance-interruption-behavior`, specify an interruption behavior.

Stop interrupted Spot Instances

You can specify that Amazon EC2 stops your Spot Instances when they are interrupted. For more information, see [Specify the interruption behavior \(p. 476\)](#).

Considerations

- Only Amazon EC2 can restart an interrupted stopped Spot Instance.
- For a Spot Instance launched by a persistent Spot Instance request: Amazon EC2 restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance (the same launch specification must be used).

- For Spot Instances launched by an EC2 Fleet or Spot Fleet of type `maintain`: After a Spot Instance is interrupted, Amazon EC2 launches a replacement instance to maintain the target capacity. Amazon EC2 finds the best Spot capacity pools based on the specified allocation strategy (`lowestPrice`, `diversified`, or `InstancePoolsToUseCount`); it does not prioritize the pool with the earlier stopped instance. Later, if the allocation strategy leads to a pool containing the earlier stopped instance, Amazon EC2 restarts the stopped instance to meet the target capacity.

For example, consider a Spot Fleet with the `lowestPrice` allocation strategy. At initial launch, a `c3.large` pool meets the `lowestPrice` criteria for the launch specification. Later, when the `c3.large` instances are interrupted, Amazon EC2 stops the instances and replenishes capacity from another pool that fits the `lowestPrice` strategy. This time, the pool happens to be a `c4.large` pool and Amazon EC2 launches `c4.large` instances to meet the target capacity. Similarly, Spot Fleet could move to a `c5.large` pool the next time. In each of these transitions, Amazon EC2 does not prioritize pools with earlier stopped instances, but rather prioritizes purely on the specified allocation strategy. The `lowestPrice` strategy can lead back to pools with earlier stopped instances. For example, if instances are interrupted in the `c5.large` pool and the `lowestPrice` strategy leads it back to the `c3.large` or `c4.large` pools, the earlier stopped instances are restarted to fulfill target capacity.

- While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and Amazon EC2 attempts to start the Spot Instance, the instance will fail to start and Amazon EC2 will terminate the stopped instance.
- You can terminate a Spot Instance while it is stopped.
- If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, Amazon EC2 terminates any associated Spot Instances that are stopped.
- While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account. For more information about how you're charged when a Spot Instance is interrupted, see [Billing for interrupted Spot Instances \(p. 484\)](#).
- Make sure that you are familiar with the implications of stopping an instance. For information about what happens when an instance is stopped, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

Prerequisites

To stop an interrupted Spot Instance, the following prerequisites must be in place:

Spot request type

Spot Instance request type – Must be `persistent`. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be `maintain`.

Root volume type

Must be an EBS volume, not an instance store volume.

Hibernate interrupted Spot Instances

You can specify that Amazon EC2 hibernates your Spot Instances when they are interrupted. For more information, see [Specify the interruption behavior \(p. 476\)](#).

When Amazon EC2 hibernates a Spot Instance, the following occurs:

- When the instance receives a signal from Amazon EC2, the agent prompts the operating system to hibernate. If the agent is not installed, or the underlying operating system doesn't support

hibernation, or there isn't enough volume space to save the instance memory, hibernation fails and Amazon EC2 stops the instance instead.

- The instance memory (RAM) is preserved on the root volume.
- The EBS volumes and private IP addresses of the instance are preserved.
- Instance store volumes and public IP addresses, other than Elastic IP addresses, are not preserved.

For information about hibernating On-Demand Instances, see [Hibernate your On-Demand Linux instance \(p. 640\)](#).

Considerations

- Only Amazon EC2 can hibernate a Spot Instance. You can't manually hibernate a Spot Instance.
- Only Amazon EC2 can resume a hibernated Spot Instance. You can't manually resume a hibernated Spot Instance.
- Amazon EC2 resumes the instance when capacity becomes available with a Spot price that is less than your specified maximum price.
- When Amazon EC2 hibernates a Spot Instance, hibernation begins immediately. You receive an interruption notice, but you do not have two minutes before the Spot Instance is interrupted.
- While the instance is in the process of hibernating, instance health checks might fail.
- When the hibernation process completes, the state of the instance is stopped.
- While the instance is hibernated, you are charged only for the EBS volumes. With EC2 Fleet and Spot Fleet, if you have many hibernated instances, you can exceed the limit on the number of EBS volumes for your account.
- Make sure that you are familiar with the implications of hibernating an instance. For information about what happens when an instance is hibernated, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

Prerequisites

To hibernate a Spot Instance, the following prerequisites must be in place:

Spot request type

Spot Instance request type – Must be `persistent`. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be `maintain`.

Supported Linux operating systems

If you use one of the following operating systems, you must [install the hibernation agent \(p. 479\)](#). Alternatively, use a supported AMI, which already includes the hibernation agent.

- Amazon Linux 2
- Amazon Linux AMI
- Ubuntu with an AWS-tuned Ubuntu kernel (`linux-aws`) greater than 4.4.0-1041

Supported Linux AMIs

The following supported AMIs include the hibernation agent.

- Amazon Linux 2
- Amazon Linux AMI 2017.09.1 or later
- Ubuntu Xenial 16.04 20171121 or later

For information about the supported Windows AMIs, see the [prerequisites](#) in the *Amazon EC2 User Guide for Windows Instances*.

Start the hibernation agent

We recommend that you use user data to start the hibernation agent at instance launch. Alternatively, you could start the agent manually. For more information, see [Start the hibernation agent at launch \(p. 480\)](#).

Supported instance families

C3, C4, C5, M4, M5, R3, R4

Instance RAM size

Must be less than 100 GB.

Root volume type

Must be an EBS volume, not an instance store volume.

EBS root volume size

Must be large enough to store the instance memory (RAM) during hibernation.

EBS root volume encryption – recommended, but not a prerequisite for Spot Instance hibernation

We strongly recommend that you use an encrypted EBS volume as the root volume, because instance memory is stored on the root volume during hibernation. This ensures that the contents of memory (RAM) are encrypted when the data is at rest on the volume and when data is moving between the instance and volume.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Encryption by default \(p. 1545\)](#).
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs \(p. 203\)](#).
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see [Encrypt an unencrypted image during copy \(p. 207\)](#) and [Copy an AMI \(p. 182\)](#).

[Install the hibernation agent on your Linux AMI](#)

You must install the hibernation agent on your AMI, unless you plan to use an AMI that already includes the agent.

The following instructions describe how to install the hibernation agent on a Linux AMI. For the instructions to install the hibernation agent on a Windows AMI, see [Install the hibernation agent on your on Windows AMI](#) in the *Amazon EC2 User Guide for Windows Instances*.

To install the hibernation agent on an Amazon Linux AMI

1. Verify that your kernel supports hibernation and update the kernel if necessary.

```
sudo yum update kernel
```

2. If your AMI doesn't include the agent, install the agent.

```
sudo yum update; sudo yum install hibagent
```

To install the hibernation agent on an Ubuntu AMI

If your AMI doesn't include the agent, install the agent. The hibernation agent is only available on Ubuntu 16.04 or later.

```
sudo apt-get install hibagent
```

Start the hibernation agent at launch

The hibernation agent must run at instance startup, whether the agent was included in your AMI or you installed it yourself.

The following instructions describe how to start the hibernation agent on a Linux instance. For the instructions to start the hibernation agent on a Windows instance, see [Start the hibernation agent at launch](#) in the *Amazon EC2 User Guide for Windows Instances*.

To start the hibernation agent on a Spot Instance

Follow the steps to request a Spot Instance using your preferred [launch method \(p. 578\)](#), and add the following to the user data.

```
#!/bin/bash
/usr/bin/enable-ec2-spot-hibernation
```

Terminate interrupted Spot Instances

When Amazon EC2 interrupts a Spot Instance, it terminates the instance by default, unless you specify a different interruption behavior, such as stop or hibernate. For more information, see [Specify the interruption behavior \(p. 476\)](#).

Prepare for interruptions

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

We recommend that you follow these best practices so that you're prepared for a Spot Instance interruption.

- Create your Spot request using an Auto Scaling group. If your Spot Instances are interrupted, the Auto Scaling group will automatically launch replacement instances. For more information, see [Auto Scaling groups with multiple instance types and purchase options](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you create your Spot request, specify the default maximum price, which is the On-Demand price. When your Spot Instances launch, you'll only pay the Spot price.
- Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at startup.
- Store important data regularly in a place that isn't affected if the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.

- Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.
- Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see [EC2 instance rebalance recommendations \(p. 472\)](#).
- Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see [Spot Instance interruption notices \(p. 481\)](#).
- While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance recommendation signals and interruption notices. You can do this by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.
- Run a controlled fault injection experiment with AWS Fault Injection Simulator to test how your application responds when your Spot Instance is interrupted. For more information, see the [Tutorial: Test Spot Instance interruptions using AWS FIS](#) in the *AWS Fault Injection Simulator User Guide*.

Spot Instance interruption notices

A *Spot Instance interruption notice* is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior, you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as a CloudWatch event and as items in the [instance metadata \(p. 726\)](#) on the Spot Instance. Events are emitted on a best effort basis.

EC2 Spot Instance interruption notice

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon CloudWatch Events. For more information about CloudWatch events, see the [Amazon CloudWatch Events User Guide](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

The following is an example of the event for Spot Instance interruption. The possible values for `instance-action` are `hibernate`, `stop`, or `terminate`.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Spot Instance Interruption Warning",

instance-action

If your Spot Instance is marked to be stopped or terminated by Amazon EC2, the `instance-action` item is present in your [instance metadata \(p. 726\)](#). Otherwise, it is not present. You can retrieve `instance-action` as follows.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" ` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/spot/instance-action
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/spot/instance-action
```

The `instance-action` item specifies the action and the approximate time, in UTC, when the action will occur.

The following example output indicates the time at which this instance will be stopped.

```
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example output indicates the time at which this instance will be terminated.

```
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, `instance-action` is not present in the instance metadata and you receive an HTTP 404 error when you try to retrieve it.

termination-time

This item is maintained for backward compatibility; you should use `instance-action` instead.

If your Spot Instance is marked for termination by Amazon EC2, the `termination-time` item is present in your instance metadata. Otherwise, it is not present. You can retrieve `termination-time` as follows.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" ` \
[ec2-user ~]$ if curl -H "X-aws-ec2-metadata-token: $TOKEN" -s http://169.254.169.254/latest/meta-data/spot/termination-time | grep -q .*T.*Z; then echo terminated; fi
```

IMDSv1

```
[ec2-user ~]$ if curl -s http://169.254.169.254/latest/meta-data/spot/termination-time \
| grep -q .*T.*Z; then echo terminated; fi
```

The `termination-time` item specifies the approximate time in UTC when the instance receives the shutdown signal. The following is example output.

2015-01-05T18:02:00Z

If Amazon EC2 is not preparing to terminate the instance, or if you terminated the Spot Instance yourself, the `termination-time` item is either not present in the instance metadata (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to `fulfilled`. The `termination-time` value remains in the instance metadata with the original approximate time, which is now in the past.

Find interrupted Spot Instances

In the console, the **Instances** pane displays all instances, including Spot Instances. You can identify a Spot Instance from the `spot` value in the **Instance lifecycle** column. The **Instance state** column indicates whether the instance is pending, running, stopping, stopped, shutting-down, or terminated. For a hibernated Spot Instance, the instance state is stopped.

To find an interrupted Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**. In the top right corner, choose the settings icon (), and under **Attribute columns**, select **Instance lifecycle**. For Spot Instances, **Instance lifecycle** is `spot`.

Alternatively, in the navigation pane, choose **Spot Requests**. You can see both Spot Instance requests and Spot Fleet requests. To view the IDs of the instances, select a Spot Instance request or a Spot Fleet request and choose the **Instances** tab. Choose an instance ID to display the instance in the **Instances** pane.

3. For each Spot Instance, you can view its state in the **Instance State** column.

To find interrupted Spot Instances (AWS CLI)

You can list your interrupted Spot Instances using the `describe-instances` command with the `--filters` parameter. To list only the instance IDs in the output, include the `--query` parameter.

```
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-
  name,Values=terminated,stopped \
  --query "Reservations[*].Instances[*].InstanceId"
```

Determine whether Amazon EC2 interrupted a Spot Instance

If a Spot Instance is stopped, hibernated, or terminated, you can use CloudTrail to see whether Amazon EC2 interrupted the Spot Instance. In AWS CloudTrail, the event name `BidEvictedEvent` indicates that Amazon EC2 interrupted the Spot Instance.

To view BidEvictedEvent events in CloudTrail

1. Open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
2. In the navigation pane, choose **Event history**.
3. In the filter drop-down, choose **Event name**, and then in the filter field to the right, enter `BidEvictedEvent`.
4. Choose `BidEvictedEvent` in the resulting list to view its details. Under **Event record**, you can find the instance ID.

For more information about using CloudTrail, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail \(p. 1018\)](#).

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you're charged for instance and EBS volume usage as follows.

Instance usage

Who interrupts the Spot Instance	Operating system	Interrupted in the first hour	Interrupted in any hour after the first hour
If you stop or terminate the Spot Instance	Windows and Linux (excluding RHEL and SUSE)	Charged for the seconds used	Charged for the seconds used
	RHEL and SUSE	Charged for the full hour even if you used a partial hour	Charged for the full hours used, and charged a full hour for the interrupted partial hour
If the Amazon EC2 interrupts the Spot Instance	Windows and Linux (excluding RHEL and SUSE)	No charge	Charged for the seconds used
	RHEL and SUSE	No charge	Charged for the full hours used, but no charge for the interrupted partial hour

EBS volume usage

While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved.

With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.

Spot placement score

The Spot placement score feature can recommend an AWS Region or Availability Zone based on your Spot capacity requirements. Spot capacity fluctuates, and you can't be sure that you'll always get the capacity that you need. A Spot placement score indicates how likely it is that a Spot request will succeed in a Region or Availability Zone.

Note

A Spot placement score does not provide any guarantees in terms of available capacity or risk of interruption. A Spot placement score serves only as a recommendation.

Benefits

You can use the Spot placement score feature for the following:

- To relocate and scale Spot compute capacity in a different Region, as needed, in response to increased capacity needs or decreased available capacity in the current Region.
- To identify the most optimal Availability Zone in which to run single-Availability Zone workloads.
- To simulate future Spot capacity needs so that you can pick an optimal Region for the expansion of your Spot-based workloads.

- [Example configurations \(p. 492\)](#)

Costs

There is no additional charge for using the Spot placement score feature.

How Spot placement score works

When you use the Spot placement score feature, you first specify your compute requirements for your Spot Instances, and then Amazon EC2 returns the top 10 Regions or Availability Zones where your Spot request is likely to succeed. Each Region or Availability Zone is scored on a scale from 1 to 10, with 10 indicating that your Spot request is highly likely to succeed, and 1 indicating that your Spot request is not likely to succeed.

To use the Spot placement score feature, follow these steps:

- [Step 1: Specify your Spot requirements \(p. 485\)](#)
- [Step 2: Filter the Spot placement score response \(p. 486\)](#)
- [Step 3: Review the recommendations \(p. 486\)](#)
- [Step 4: Use the recommendations \(p. 487\)](#)

Step 1: Specify your Spot requirements

First, you specify your desired target Spot capacity and your compute requirements, as follows:

1. **Specify the target Spot capacity, and optionally the target capacity unit.**

You can specify your desired target Spot capacity in terms of the number of instances or vCPUs, or in terms of the amount of memory in MiB. To specify the target capacity in number of vCPUs or amount of memory, you must specify the target capacity unit as `vcpu` or `memory-mib`. Otherwise, it defaults to number of instances.

By specifying your target capacity in terms of the number of vCPUs or the amount of memory, you can use these units when counting the total capacity. For example, if you want to use a mix of instances of different sizes, you can specify the target capacity as a total number of vCPUs. The Spot placement score feature then considers each instance type in the request by its number of vCPUs, and counts the total number of vCPUs rather than the total number of instances when totaling up the target capacity.

For example, say you specify a total target capacity of 30 vCPUs, and your instance type list consists of c5.xlarge (4 vCPUs), m5.2xlarge (8 vCPUs), and r5.large (2 vCPUs). To achieve a total of 30 vCPUs, you could get a mix of 2 c5.xlarge (2*4 vCPUs), 2 m5.2xlarge (2*8 vCPUs), and 3 r5.large (3*2 vCPUs).

2. Specify instance types or instance attributes.

You can either specify the instance types to use, or you can specify the instance attributes that you need for your compute requirements, and then let Amazon EC2 identify the instance types that have those attributes. This is known as attribute-based instance type selection.

You can't specify both instance types and instance attributes in the same Spot placement score request.

If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types.

For examples of different ways to specify your Spot requirements, see [Example configurations \(p. 492\)](#).

Step 2: Filter the Spot placement score response

Amazon EC2 calculates the Spot placement score for each Region or Availability Zone, and returns either the top 10 Regions or the top 10 Availability Zones where your Spot request is likely to succeed. The default is to return a list of scored Regions. If you plan to launch all of your Spot capacity into a single Availability Zone, then it's useful to request a list of scored Availability Zones.

You can specify a Region filter to narrow down the Regions that will be returned in the response.

You can combine the Region filter and a request for scored Availability Zones. In this way, the scored Availability Zones are confined to the Regions for which you've filtered. To find the highest-scored Availability Zone in a Region, specify only that Region, and the response will return a scored list of all of the Availability Zones in that Region.

Step 3: Review the recommendations

The Spot placement score for each Region or Availability Zone is calculated based on the target capacity, the composition of the instance types, the historical and current Spot usage trends, and the time of the request. Because Spot capacity is constantly fluctuating, the same Spot placement score request can yield different scores when calculated at different times.

Regions and Availability Zones are scored on a scale from 1 to 10. A score of 10 indicates that your Spot request is highly likely—but not guaranteed—to succeed. A score of 1 indicates that your Spot request is not likely to succeed at all. The same score might be returned for different Regions or Availability Zones.

If low scores are returned, you can edit your compute requirements and recalculate the score. You can also request Spot placement score recommendations for the same compute requirements at different times of the day.

Step 4: Use the recommendations

A Spot placement score is only relevant if your Spot request has exactly the same configuration as the Spot placement score configuration (target capacity, target capacity unit, and instance types or instance attributes), and is configured to use the capacity-optimized allocation strategy. Otherwise, the likelihood of getting available Spot capacity will not align with the score.

While a Spot placement score serves as a guideline, and no score guarantees that your Spot request will be fully or partially fulfilled, you can use the following information to get the best results:

- **Use the same configuration** – The Spot placement score is relevant only if the Spot request configuration (target capacity, target capacity unit, and instance types or instance attributes) in your Auto Scaling group, EC2 Fleet, or Spot Fleet is the same as what you entered to get the Spot placement score.

If you used attribute-based instance type selection in your Spot placement score request, you can use attribute-based instance type selection to configure your Auto Scaling group, EC2 Fleet, or Spot Fleet. For more information, see [Creating an Auto Scaling group with a set of requirements on the instance types used](#), [Attribute-based instance type selection for EC2 Fleet \(p. 801\)](#), and [Attribute-based instance type selection for Spot Fleet \(p. 842\)](#).

Note

If you specified your target capacity in terms of the number of vCPUs or the amount of memory, and you specified instance types in your Spot placement score configuration, note that you can't currently create this configuration in your Auto Scaling group, EC2 Fleet, or Spot Fleet. Instead, you must manually set the instance weighting by using the `WeightedCapacity` parameter.

- **Use the capacity-optimized allocation strategy** – Any score assumes that your fleet request will be configured to use all Availability Zones (for requesting capacity across Regions) or a single Availability Zone (if requesting capacity in one Availability Zone) and the capacity-optimized Spot allocation strategy for your request for Spot capacity to succeed. If you use other allocation strategies, such as lowest-price, the likelihood of getting available Spot capacity will not align with the score.
- **Act on a score immediately** – The Spot placement score recommendation reflects the available Spot capacity at the time of the request, and the same configuration can yield different scores when calculated at different times due to Spot capacity fluctuations. While a score of 10 means that your Spot capacity request is highly likely—but not guaranteed—to succeed, for best results we recommend that you act on a score immediately. We also recommend that you get a fresh score each time you attempt a capacity request.

Limitations

- **Target capacity limit** – Your Spot placement score target capacity limit is based on your recent Spot usage, while accounting for potential usage growth. If you have no recent Spot usage, we provide you with a low default limit aligned with your Spot request limit.
- **Request configurations limit** – We can limit the number of new request configurations within a 24-hour period if we detect patterns not associated with the intended use of the Spot placement score feature. If you reach the limit, you can retry the request configurations that you've already used, but you can't specify new request configurations until the next 24-hour period.
- **Minimum number of instance types** – If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types. Instance types are considered different if they have a different name. For example, m5.8xlarge, m5a.8xlarge, and m5.12xlarge are all considered different.

Required IAM permission

By default, IAM identities (users, roles, or groups) don't have permission to use the Spot placement score feature. To allow IAM identities to use the Spot placement score feature, you must create an IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action. You then attach the policy to the IAM identities that require this permission.

The following is an example IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "ec2:GetSpotPlacementScores",  
            "Resource": "*"  
        }  
    ]  
}
```

For information about editing an IAM policy, see [Editing IAM policies](#) in the *IAM User Guide*.

Calculate a Spot placement score

You can calculate a Spot placement score by using the Amazon EC2 console or the AWS CLI.

Calculate a Spot placement score by specifying instance attributes (console)

To calculate a Spot placement score by specifying instance attributes

1. Open the Spot console at <https://console.aws.amazon.com/ec2spot>.
2. Choose **Spot placement score**.
3. Choose **Enter requirements**.
4. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
5. For **Instance type requirements**, to specify your compute requirements and let Amazon EC2 identify the optimal instance types with these requirements, choose **Specify instance attributes that match your compute requirements**.
6. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum, No maximum**, or both.
7. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum, No maximum**, or both.
8. For **CPU architecture**, select the required instance architecture.
9. (Optional) For **Additional instance attributes**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

10. (Optional) To view the instance types with your specified attributes, expand **Preview matching instance types**. To exclude instance types from being used in the placement evaluation, select the instances and then choose **Exclude selected instance types**.
11. Choose **Load placement scores**, and review the results.
12. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
13. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
14. (Optional) To edit your compute requirements and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate a Spot placement score by specifying instance types (console)

To calculate a Spot placement score by specifying instance types

1. Open the Spot console at <https://console.aws.amazon.com/ec2spot>.
2. Choose **Spot placement score**.
3. Choose **Enter requirements**.
4. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
5. For **Instance type requirements**, to specify the instance types to use, choose **Manually select instance types**.
6. Choose **Select instance types**, select the instance types to use, and then choose **Select**. To quickly find instance types, you can use the filter bar to filter the instance types by different properties.
7. Choose **Load placement scores**, and review the results.
8. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
9. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
10. (Optional) To edit the list of instance types and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate the Spot placement score (AWS CLI)

To calculate the Spot placement score

1. (Optional) To generate all of the possible parameters that can be specified for the Spot placement score configuration, use the [get-spot-placement-scores](#) command and the `--generate-cli-skeleton` parameter.

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

- a. For `TargetCapacity`, enter your desired Spot capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).
- b. For `TargetCapacityUnitType`, enter the unit for the target capacity. If you omit this parameter, it defaults to `units`.

Valid values: `units` (which translates to number of instances) | `vcpu` | `memory-mib`

- c. For `SingleAvailabilityZone`, specify `true` for a response that returns a list of scored Availability Zones. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone. If you omit this parameter, it defaults to `false`, and the response returns a list of scored Regions.
- d. (Optional) For `RegionNames`, specify the Regions to use as a filter. You must specify the Region code, for example, `us-east-1`.

With a Region filter, the response returns only the Regions that you specify. If you specified `true` for `SingleAvailabilityZone`, the response returns only the Availability Zones in the specified Regions.

- e. You can include either `InstanceTypes` or `InstanceRequirements`, but not both in the same configuration.

Specify one of the following in your JSON configuration:

- To specify a list of instance types, specify the instance types in the `InstanceTypes` parameter. Specify at least three different instance types. If you specify only one or two instance types, Spot placement score returns a low score. For the list of instance types, see [Amazon EC2 Instance Types](#).
- To specify the instance attributes so that Amazon EC2 will identify the instance types that match those attributes, specify the attributes that are located in the `InstanceRequirements` structure.

You must provide values for `VcpuCount`, `MemoryMiB`, and `CpuManufacturers`. You can omit the other attributes; when omitted, the default values are used. For a description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

For example configurations, see [Example configurations \(p. 492\)](#).

3. To get the Spot placement score for the requirements that you specified in the JSON file, use the [get-spot-placement-scores](#) command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter.

```
aws ec2 get-spot-placement-scores \
--region us-east-1 \
```

```
--cli-input-json file://file_name.json
```

Example output if SingleAvailabilityZone is set to `false` or omitted (if omitted, it defaults to `false`) – a scored list of Regions is returned

Example configurations

When using the AWS CLI, you can use the following example configurations.

Example configurations

- [Example: Specify instance types and target capacity \(p. 492\)](#)
- [Example: Specify instance types, and target capacity in terms of memory \(p. 493\)](#)
- [Example: Specify attributes for attribute-based instance type selection \(p. 493\)](#)
- [Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones \(p. 494\)](#)

Example: Specify instance types and target capacity

The following example configuration specifies three different instance types and a target Spot capacity of 500 Spot Instances.

```
{

    "TargetCapacity": 500  
}
```

Example: Specify instance types, and target capacity in terms of memory

The following example configuration specifies three different instance types and a target Spot capacity of 500,000 MiB of memory, where the number of Spot Instances to launch must provide a total of 500,000 MiB of memory.

```
{

Example: Specify attributes for attribute-based instance type selection

The following example configuration is configured for attribute-based instance type selection, and is followed by a text explanation of the example configuration.

```
{  
    "TargetCapacity": 5000,  
    "TargetCapacityUnitType": "vcpu",  
    "InstanceRequirementsWithMetadata": {  
        "ArchitectureTypes": ["arm64"],  
        "VirtualizationTypes": ["hvm"],  
        "InstanceRequirements": {  
            "VCpuCount": {  
                "Min": 1,

            },  
            "MemoryMiB": {  
                "Min": 512  
            }  
        }  
    }  
}
```

InstanceRequirementsWithMetadata

To use attribute-based instance type selection, you must include the `InstanceRequirementsWithMetadata` structure in your configuration, and specify the desired attributes for the Spot Instances.

In the preceding example, the following required instance attributes are specified:

- `ArchitectureTypes` – The architecture type of the instance types must be `arm64`.
- `VirtualizationTypes` – The virtualization type of the instance types must be `hvm`.
- `VCpuCount` – The instance types must have a minimum of 1 and a maximum of 12 vCPUs.
- `MemoryMiB` – The instance types must have a minimum of 512 MiB of memory. By omitting the `Max` parameter, you are indicating that there is no maximum limit.

Note that there are several other optional attributes that you can specify. For the list of attributes, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

TargetCapacityUnitType

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is `vcpu`, which together specify a desired

target capacity of 5000 vCPUs, where the number of Spot Instances to launch must provide a total of 5000 vCPUs.

Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

The following example configuration is configured for attribute-based instance type selection. By specifying "SingleAvailabilityZone": true, the response will return a list of scored Availability Zones.

```
{  
    "TargetCapacity": 1000,  
    "TargetCapacityUnitType": "vcpu",  
    "SingleAvailabilityZone": true,  
    "InstanceRequirementsWithMetadata": {  
        "ArchitectureTypes": ["arm64"],  
        "VirtualizationTypes": ["hvm"],  
        "InstanceRequirements": {  
            "VCpuCount": {  
                "Min": 1,  
                "Max": 12  
            },  
            "MemoryMiB": {  
                "Min": 512  
            }  
        }  
    }  
}
```

Spot Instance data feed

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.

Data feed files arrive in your bucket typically once an hour, and each hour of usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2 can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

Note

If you don't have a Spot Instance running during a certain hour, you don't receive a data feed file for that hour.

Spot Instance data feed is supported in all AWS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US), and the [Regions that are disabled by default](#).

Contents

- [Data feed file name and format \(p. 494\)](#)
- [Amazon S3 bucket requirements \(p. 495\)](#)
- [Subscribe to your Spot Instance data feed \(p. 496\)](#)
- [Describe your Spot Instance data feed \(p. 496\)](#)
- [Delete your Spot Instance data feed \(p. 496\)](#)

Data feed file name and format

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

`bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-id.gz`

For example, if your bucket name is `my-bucket-name` and your prefix is `my-prefix`, your file names are similar to the following:

`my-bucket-name.s3.amazonaws.com/my-prefix/111122223333.2019-03-17-20.001.pwBdGTJG.gz`

For more information about bucket names, see [Rules for bucket naming in the Amazon Simple Storage Service User Guide](#).

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

Field	Description
Timestamp	The timestamp used to determine the price charged for this instance usage.
UsageType	The type of usage and instance type being charged for. For <code>m1.small</code> Spot Instances, this field is set to <code>SpotUsage</code> . For all other instance types, this field is set to <code>SpotUsage:{instance-type}</code> . For example, <code>SpotUsage:c1.medium</code> .
Operation	The product being charged for. For Linux Spot Instances, this field is set to <code>RunInstances</code> . For Windows Spot Instances, this field is set to <code>RunInstances:0002</code> . Spot usage is grouped according to Availability Zone.
InstanceID	The ID of the Spot Instance that generated this instance usage.
MyBidID	The ID for the Spot Instance request that generated this instance usage.
MyMaxPrice	The maximum price specified for this Spot request.
MarketPrice	The Spot price at the time specified in the <code>Timestamp</code> field.
Charge	The price charged for this instance usage.
Version	The version included in the data feed file name for this record.

Amazon S3 bucket requirements

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files. Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have `FULL_CONTROL` permission to the bucket, which includes permission for the `s3:GetBucketAcl` and `s3:PutBucketAcl` actions.

If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.

- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account `FULL_CONTROL` permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket.

Note

If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.

- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has `FULL_CONTROL` permission to the data files. The AWS data feed account has read and write permissions.
- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.

Subscribe to your Spot Instance data feed

To subscribe to your data feed, use the [create-spot-datafeed-subscription](#) command.

```
aws ec2 create-spot-datafeed-subscription \
  --bucket my-bucket-name \
  [--prefix my-prefix]
```

The following is example output:

```
{  
  "SpotDatafeedSubscription": {  
    "OwnerId": "111122223333",  
    "Bucket": "my-bucket-name",  
    "Prefix": "my-prefix",  
    "State": "Active"  
  }  
}
```

Describe your Spot Instance data feed

To describe your data feed subscription, use the [describe-spot-datafeed-subscription](#) command.

```
aws ec2 describe-spot-datafeed-subscription
```

The following is example output:

```
{  
  "SpotDatafeedSubscription": {  
    "OwnerId": "123456789012",  
    "Prefix": "spotdata",  
    "Bucket": "my-s3-bucket",  
    "State": "Active"  
  }  
}
```

Delete your Spot Instance data feed

To delete your data feed, use the [delete-spot-datafeed-subscription](#) command.

```
aws ec2 delete-spot-datafeed-subscription
```

Spot Instance limits

There is a limit on the number of running and requested Spot Instances per AWS account per Region. Spot Instance limits are managed in terms of the *number of virtual central processing units (vCPUs)* that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance

requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU limit until Amazon EC2 detects the Spot Instance terminations and closes the requests.

There are seven Spot Instance limits:

- All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests
- All DL Spot Instance Requests
- All F Spot Instance Requests
- All G and VT Spot Instance Requests
- All Inf Spot Instance Requests
- All P Spot Instance Requests
- All X Spot Instance Requests

Each limit specifies the vCPU limit for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

With vCPU limits, you can use your limit in terms of the number of vCPUs that are required to launch any combination of instance types that meet your changing application needs. For example, say your All Standard Spot Instance Requests limit is 256 vCPUs, you could request 32 m5.2xlarge Spot Instances (32 x 8 vCPUs) or 16 c5.4xlarge Spot Instances (16 x 16 vCPUs), or a combination of any Standard Spot Instance types and sizes that total 256 vCPUs.

Monitor Spot Instance limits and usage

You can view and manage your Spot Instance limits using the following:

- The [Limits page](#) in the Amazon EC2 console
- The [Amazon EC2 Services quotas page](#) in the Service Quotas console
- The [get-service-quota](#) AWS CLI

For more information, see [Amazon EC2 service quotas \(p. 1706\)](#) in the *Amazon EC2 User Guide for Linux Instances* and [Viewing service quotas](#) in the *Service Quotas User Guide*.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against limits. You can also configure alarms to warn about approaching limits. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Request a Spot Instance limit increase

Even though Amazon EC2 automatically increases your Spot Instance limits based on your usage, you can request a limit increase if necessary. For example, if you intend to launch more Spot Instances than your current limit allows, you can request a limit increase. You can also request a limit increase if you submit a Spot Instance request and you receive the error `Max spot instance count exceeded`.

To request a Spot Instance limit increase

1. Open the **Create case, Service limit increase** form in the Support Center console at <https://console.aws.amazon.com/support/home#/case/create>.

2. For **Limit type**, choose **EC2 Spot Instances**.
3. For **Region**, select the required Region.
4. For **Primary instance type**, select the Spot Instance limit for which you want to request a limit increase.
5. For **New limit value**, enter the total number of vCPUs that you want to run concurrently. To determine the total number of vCPUs that you need, see [Amazon EC2 Instance Types](#) to find the number of vCPUs of each instance type.
6. (Conditional) You must create a separate limit request for each Spot Instance limit. To request an increase for another Spot Instance limit, choose **Add another request** and repeat steps 4 and 5 in this procedure.
7. For **Use case description**, enter your use case, and then choose **Submit**.

For more information about viewing limits and requesting a limit increase, see [Amazon EC2 service quotas \(p. 1706\)](#).

Burstable performance instances

If you launch your Spot Instances using a [burstable performance instance type \(p. 266\)](#), and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in [Standard mode \(p. 281\)](#) to avoid paying higher costs. If you launch burstable performance Spot Instances in [Unlimited mode \(p. 274\)](#) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see [When to use unlimited mode versus fixed CPU \(p. 276\)](#).

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use [Unlimited mode \(p. 274\)](#) for T2 Spot Instances, or use an instance type with dedicated CPU.

Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server with EC2 instance capacity fully dedicated to your use. Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, Microsoft SQL Server, SUSE, and Linux Enterprise Server.

For information about the configurations supported on Dedicated Hosts, see [Dedicated Hosts Configuration](#).

Differences between Dedicated Hosts and Dedicated Instances

Dedicated Hosts and Dedicated Instances can both be used to launch Amazon EC2 instances onto physical servers that are dedicated for your use.

There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some differences between the two. The following table highlights some of the key differences between Dedicated Hosts and Dedicated Instances:

	Dedicated Host	Dedicated Instance
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Host recovery (p. 526) .	Supported
Bring Your Own License (BYOL)	Supported	Not supported

Bring your own license

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment.
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the [VM Import/Export User Guide](#).
3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.

- When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server.

Note

To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see [Track configuration changes \(p. 530\)](#).

Dedicated Host instance capacity

Support for multiple instance sizes on the same Dedicated Host is available for the following instance families: T3, A1, C5, M5, R5, C5n, R5n, and M5n. Other instance families support only a single instance size on the same Dedicated Host.

For example, when you allocate an R5 Dedicated Host, it has 2 sockets and 48 physical cores on which you can run different instance sizes, such as `r5.2xlarge` and `r5.4xlarge`, up to the core capacity associated with the host. However, for each instance family, there is a limit on the number of instances that can be run for each instance size. For example, an R5 Dedicated Host supports up to 2 `r5.8xlarge` instances, which uses 32 of the physical cores. Additional R5 instances of another size can then be used to fill the host to core capacity. For the supported number of instance sizes for each instance family, see [Dedicated Hosts Configuration](#).

The following table shows examples of different instance size combinations that you can run on a Dedicated Host.

Instance family	Example instance size combinations
R5	<ul style="list-style-type: none">Example 1: 4 x <code>r5.4xlarge</code> + 4 x <code>r5.2xlarge</code>Example 2: 1 x <code>r5.12xlarge</code> + 1 x <code>r5.4xlarge</code> + 1 x <code>r5.2xlarge</code> + 5 x <code>r5.xlarge</code> + 2 x <code>r5.large</code>
C5	<ul style="list-style-type: none">Example 1: 1 x <code>c5.9xlarge</code> + 2 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code>Example 2: 4 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code> + 2 x <code>c5.large</code>
M5	<ul style="list-style-type: none">Example 1: 4 x <code>m5.4xlarge</code> + 4 x <code>m5.2xlarge</code>Example 2: 1 x <code>m5.12xlarge</code> + 1 x <code>m5.4xlarge</code> + 1 x <code>m5.2xlarge</code> + 5 x <code>m5.xlarge</code> + 2 x <code>m5.large</code>

For more information about the instance families and instance size configurations supported on Dedicated Hosts, see the [Dedicated Hosts Configuration Table](#).

Burstable T3 instances on Dedicated Hosts

Dedicated Hosts support burstable performance T3 instances. T3 instances provide a cost-efficient way of using your eligible BYOL license software on dedicated hardware. The smaller vCPU footprint of T3 instances enables you to consolidate your workloads on fewer hosts and maximize your per-core license utilization.

T3 Dedicated Hosts are best suited for running BYOL software with low to moderate CPU utilization. This includes eligible per-socket, per-core, or per-VM software licenses, such as Windows Server, Windows Desktop, SQL Server, SUSE Enterprise Linux Server, Red Hat Enterprise Linux, and Oracle Database. Examples of workloads suited for T3 Dedicated Hosts are small and medium databases, virtual desktops,

development and test environments, code repositories, and product prototypes. T3 Dedicated Hosts are not recommended for workloads with sustained high CPU utilization or for workloads that experience correlated CPU bursts simultaneously.

T3 instances on Dedicated Hosts use the same credit model as T3 instances on shared tenancy hardware. However, they support the `standard` credit mode only; they do not support the `unlimited` credit mode. In standard mode, T3 instances on Dedicated Hosts *earn*, *spend*, and *accrue* credits in the same way as burstable instances on shared tenancy hardware. They provide a baseline CPU performance with the ability to burst above the baseline level. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. When the accrued credits are depleted, CPU utilization is lowered to the baseline level. For more information about standard mode, see [How standard burstable performance instances work \(p. 282\)](#).

T3 Dedicated Hosts support all of the features offered by Amazon EC2 Dedicated Hosts, including multiple instance sizes on a single host, Host resource groups, and BYOL.

Supported T3 instance sizes and configurations

T3 Dedicated Hosts run general purpose burstable T3 instances that share CPU resources of the host by providing a baseline CPU performance and the ability to burst to a higher level when needed. This enables T3 Dedicated Hosts, which have 48 cores, to support up to a maximum of 192 instances per host. In order to efficiently utilize the host's resources and to provide the best instance performance, the Amazon EC2 instance placement algorithm automatically calculates the supported number of instances and instance size combinations that can be launched on the host.

T3 Dedicated Hosts support multiple instance types on the same host. All T3 instance sizes are supported on Dedicated Hosts. You can run different combinations of T3 instances up to the CPU limit of the host.

The following table lists the supported instance types, summarizes the performance of each instance type, and indicates the maximum number of instances of each size that can be launched.

Instance type	vCPUs	Memory (GiB)	Baseline CPU utilization per vCPU	Network burst bandwidth (Gbps)	Amazon EBS burst bandwidth (Mbps)	Max number of instances per Dedicated Host
t3.nano	0.5	5%	5	Up to 2,085	192	
t3.micro	1	10%	5	Up to 2,085	192	
t3.small	2	20%	5	Up to 2,085	192	
t3.medium	4	20%	5	Up to 2,085	192	
t3.large	8	30%	5	2,780	96	
t3.xlarge	16	40%	5	2,780	48	
t3.2xlarge	32	40%	5	2,780	24	

Monitor CPU utilization for T3 Dedicated Hosts

You can use the `DedicatedHostCPUUtilization` Amazon CloudWatch metric to monitor the vCPU utilization of a Dedicated Host. The metric is available in the `EC2` namespace and `Per-Host-Metrics` dimension. For more information, see [Dedicated Host metrics \(p. 982\)](#).

Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL, SUSE Linux, and SQL Server on Dedicated Hosts, you must bring your own AMIs. RHEL, SUSE Linux, and SQL Server AMIs that are offered by AWS or that are available on AWS Marketplace can't be used with Dedicated Hosts. For more information on how to create your own AMI, see [Bring your own license \(p. 499\)](#).

This restriction does not apply to hosts allocated for high memory instances (`u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- Up to two On-Demand Dedicated Hosts per instance family, per Region can be allocated. It is possible to request a limit increase: [Request to Raise Allocation Limit on Amazon EC2 Dedicated Hosts](#).
- The instances that run on a Dedicated Host can only be launched in a VPC.
- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see [Creating a Launch Template for an Auto Scaling Group](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Amazon RDS instances are not supported.
- The AWS Free Usage tier is not available for Dedicated Hosts.
- Instance placement control refers to managing instance launches onto Dedicated Hosts. You cannot launch Dedicated Hosts into placement groups.

Pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options

- [On-Demand Dedicated Hosts \(p. 502\)](#)
- [Dedicated Host Reservations \(p. 502\)](#)
- [Savings Plans \(p. 503\)](#)
- [Pricing for Windows Server on Dedicated Hosts \(p. 503\)](#)

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see [Amazon EC2 Dedicated Hosts On-Demand Pricing](#).

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see [Release Dedicated Hosts \(p. 517\)](#).

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:

- **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.
- **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.
- **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (`m4.xlarge`, `m4.medium`, and `m4.large`) you can associate a single `m4` reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see [Amazon EC2 Dedicated Hosts Pricing](#).

Savings Plans

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the [AWS Savings Plans User Guide](#).

Pricing for Windows Server on Dedicated Hosts

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on [current generation instance types \(p. 241\)](#) only. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

Work with Dedicated Hosts

To use a Dedicated Host, you first allocate hosts for use in your account. You then launch instances onto the hosts by specifying *host tenancy* for the instance. You must select a specific host for the instance to launch on to, or you can allow it to launch on to any host that has auto-placement enabled and matches its instance type. When an instance is stopped and restarted, the *Host affinity* setting determines whether it's restarted on the same, or a different, host.

If you no longer need an On-Demand host, you can stop the instances running on the host, direct them to launch on a different host, and then *release* the host.

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see [Host Resource Groups](#) in the [AWS License Manager User Guide](#).

Allocate Dedicated Hosts

To begin using Dedicated Hosts, you must allocate Dedicated Hosts in your account using the Amazon EC2 console or the command line tools. After you allocate the Dedicated Host, the Dedicated Host capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

Support for multiple instance sizes of the same instance family on the same Dedicated Host is available for the following instance families: `c5`, `m5`, `r5`, `c5n`, `r5n`, and `m5n`. Other instance families support only one instance size on the same Dedicated Host.

Due to a hardware limitation with N-type Dedicated Hosts, such as `C5n`, `M5n`, and `R5n`, you cannot mix smaller instance sizes (`large`, `xlarge`, and `2xlarge`) with larger instance sizes (`4xlarge`, `9xlarge`, `18xlarge`, and `.meta1`). If you require smaller and larger instance sizes on N-type hosts at the same time, you must allocate separate hosts for the smaller and larger instance sizes.

You can allocate a Dedicated Host using the following methods.

New console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts** and then choose **Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
 - To configure the Dedicated Host to support multiple instance types in the selected instance family, for **Support multiple instance types**, choose **Enable**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the `m5` instance family and choose this option, you can launch `m5.xlarge` and `m5.4xlarge` instances onto the Dedicated Host.
 - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the

instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify `m5.4xlarge` as the supported instance type, you can launch only `m5.4xlarge` instances onto the Dedicated Host.

5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity \(p. 509\)](#).
7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see [Host recovery \(p. 526\)](#).
8. For **Quantity**, enter the number of Dedicated Hosts to allocate.
9. (Optional) Choose **Add new tag** and enter a tag key and a tag value.
10. Choose **Allocate**.

Old console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts, Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
 - To configure the Dedicated Host to support multiple instance types in the selected instance family, select **Support multiple instance types**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the `m5` instance family and choose this option, you can launch `m5.xlarge` and `m5.4xlarge` instances onto the Dedicated Host. The instance family must be powered by the Nitro System.
 - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify `m5.4xlarge` as the supported instance type, you can launch only `m5.4xlarge` instances onto the Dedicated Host.
5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity \(p. 509\)](#).
7. To enable host recovery for the Dedicated Host, for **Host recovery** choose **Enable**. For more information, see [Host recovery \(p. 526\)](#).
8. For **Quantity**, enter the number of Dedicated Hosts to allocate.
9. (Optional) Choose **Add Tag** and enter a tag key and a tag value.
10. Choose **Allocate host**.

AWS CLI

To allocate a Dedicated Host

Use the `allocate-hosts` AWS CLI command. The following command allocates a Dedicated Host that supports multiple instance types from the `m5` instance family in `us-east-1a` Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
aws ec2 allocate-hosts --instance-family "m5" --availability-zone "us-east-1a" --auto-placement "off" --host-recovery "on" --quantity 1
```

The following command allocates a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enables host recovery, and applies a tag with a key of purpose and a value of production.

```
aws ec2 allocate-hosts --instance-type "m4.large" --availability-zone "eu-west-1a" --auto-placement "on" --host-recovery "on" --quantity 1 --tag-specifications 'ResourceType=dedicated-host,Tags=[{Key=purpose,Value=production}]'
```

PowerShell

To allocate a Dedicated Host

Use the [New-EC2Host](#) AWS Tools for Windows PowerShell command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
PS C:\> New-EC2Host -InstanceFamily m5 -AvailabilityZone us-east-1a -AutoPlacement Off -HostRecovery On -Quantity 1
```

The following commands allocate a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enable host recovery, and apply a tag with a key of purpose and a value of production.

The TagSpecification parameter used to tag a Dedicated Host on creation requires an object that specifies the type of resource to be tagged, the tag key, and the tag value. The following commands create the required object.

```
PS C:\> $tag = @{ Key="purpose"; Value="production" }
PS C:\> $tagspec = new-object Amazon.EC2.Model.TagSpecification
PS C:\> $tagspec.ResourceType = "dedicated-host"
PS C:\> $tagspec.Tags.Add($tag)
```

The following command allocates the Dedicated Host and applies the tag specified in the \$tagspec object.

```
PS C:\> New-EC2Host -InstanceType m4.large -AvailabilityZone eu-west-1a -AutoPlacement On -HostRecovery On -Quantity 1 -TagSpecification $tagspec
```

Launch instances onto a Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with host tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

Note

The instances launched onto Dedicated Hosts can only be launched in a VPC. For more information, see [Introduction to VPC](#).

Before you launch your instances, take note of the limitations. For more information, see [Dedicated Hosts restrictions \(p. 502\)](#).

You can launch an instance onto a Dedicated Host using the following methods.

Console

To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions, Launch Instance(s) onto Host**.
4. Select an AMI from the list. SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.
5. On the **Choose an Instance Type** page, select the instance type to launch and then choose **Next: Configure Instance Details**.

If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.

If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. On the **Configure Instance Details** page, configure the instance settings to suit your needs, and then for **Affinity**, choose one of the following options:
 - **Off**—The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - **Host**—If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity \(p. 509\)](#).

The **Tenancy** and **Host** options are pre-configured based on the host that you selected.

7. Choose **Review and Launch**.
8. On the **Review Instance Launch** page, choose **Launch**.
9. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

To launch an instance onto a Dedicated Host using the Launch Instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances, Launch Instance**.
3. Select an AMI from the list. SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.
4. Select the type of instance to launch and choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, configure the instance settings to suit your needs, and then configure the following settings, which are specific to a Dedicated Host:
 - Tenancy—Choose **Dedicated Host - Launch this instance on a Dedicated Host**.
 - Host—Choose either **Use auto-placement** to launch the instance on any Dedicated Host that has auto-placement enabled, or select a specific Dedicated Host in the list. The list displays only Dedicated Hosts that support the selected instance type.
 - Affinity—Choose one of the following options:
 - **Off**—The instance launches onto the specified host, but it is not guaranteed to restart on it if stopped.
 - **Host**—If stopped, the instance always restarts on the specified host.

For more information, see [Understand auto-placement and affinity \(p. 509\)](#).

If you are unable to see these settings, check that you have selected a VPC in the **Network** menu.

6. Choose **Review and Launch**.
7. On the **Review Instance Launch** page, choose **Launch**.
8. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

AWS CLI

To launch an instance onto a Dedicated Host

Use the [run-instances](#) AWS CLI command and specify the instance affinity, tenancy, and host in the `Placement request` parameter.

PowerShell

To launch an instance onto a Dedicated Host

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command and specify the instance affinity, tenancy, and host in the `Placement request` parameter.

[Launch instances into a host resource group](#)

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not have a host with available instance capacity, Amazon EC2 automatically allocates a new host in the host resource group, and then launches the instance onto that host. For more information, see [Host Resource Groups](#) in the *AWS License Manager User Guide*.

Requirements and limits

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

You can launch an instance into a host resource group using the following methods.

New console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, **Launch Instances**.
3. Select an AMI.
4. Select the type of instance to launch and choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, configure the instance settings to suit your needs, and then do the following:
 - a. For **Tenancy**, choose **Dedicated Host**.

- b. For **Host resource group**, choose **Launch instance into a host resource group**.
 - c. For **Host resource group name**, choose the host resource group in which to launch the instance.
6. Choose **Review and Launch**.
 7. On the **Review Instance Launch** page, choose **Launch**.
 8. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

Old console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, **Launch Instance**.
3. Select an AMI.
4. Select the type of instance to launch and choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, configure the instance settings to suit your needs, and then do the following:
 - a. For **Tenancy**, choose **Dedicated Host**.
 - b. For **Host resource group**, choose **Launch instance into a host resource group**.
 - c. For **Host resource group name**, choose the host resource group in which to launch the instance.
6. Choose **Review and Launch**.
7. On the **Review Instance Launch** page, choose **Launch**.
8. When prompted, select an existing key pair or create a new one, and then choose **Launch Instances**.

AWS CLI

To launch an instance into a host resource group

Use the [run-instances](#) AWS CLI command, and in the `Placement` request parameter, omit the `Tenancy` option and specify the host resource group ARN.

PowerShell

To launch an instance into a host resource group

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command, and in the `Placement` request parameter, omit the `Tenancy` option and specify the host resource group ARN.

Understand auto-placement and affinity

Placement control for Dedicated Hosts happens on both the instance level and host level.

Auto-placement

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When the auto-placement of a Dedicated Host is *disabled*, it only accepts *Host* tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When the auto-placement of a Dedicated Host is *enabled*, it accepts any untargeted instance launches that match its instance type configuration.

When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific HostId enables it to launch on any Dedicated Host that has auto-placement *enabled* and that matches its instance type.

Host affinity

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to `Host`, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to `Off`, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

Modify Dedicated Host auto-placement

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account, using one of the following methods.

New console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select a host and choose **Actions, Modify host**.
4. For **Instance auto-placement**, choose **Enable** to enable auto-placement, or clear **Enable** to disable auto-placement. For more information, see [Understand auto-placement and affinity \(p. 509\)](#).
5. Choose **Save**.

Old console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions, Modify Auto-Placement**.
4. On the Modify Auto-placement window, for **Allow instance auto-placement**, choose **Yes** to enable auto-placement, or choose **No** to disable auto-placement. For more information, see [Understand auto-placement and affinity \(p. 509\)](#).
5. Choose **Save**.

AWS CLI

To modify the auto-placement of a Dedicated Host

Use the `modify-hosts` AWS CLI command. The following example enables auto-placement for the specified Dedicated Host.

```
aws ec2 modify-hosts --auto-placement on --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the auto-placement of a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command. The following example enables auto-placement for the specified Dedicated Host.

```
PS C:\> Edit-EC2Host --AutoPlacement 1 --HostId h-012a3456b7890cdef
```

Modify the supported instance types

Support for multiple instance types on the same Dedicated Host is available for the following instance families: `c5`, `m5`, `r5`, `c5n`, `r5n`, and `m5n`. Other instance families support only a single instance type on the same Dedicated Host.

You can allocate a Dedicated Host using the following methods.

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the pending state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the pending state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the `m5` instance family to support only `m5.1.large` instances, the Dedicated Host must either have no running instances, or it must have only `m5.1.large` instances running on it.

You can modify the supported instance types using one of the following methods.

New console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions, Modify host**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
 - If the Dedicated Host currently supports a specific instance type, **Support multiple instance types** is not enabled, and **Instance type** lists the supported instance type. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, choose **Enable**.

You must first stop all instances running on the host before modifying it to support multiple instance types.

- If the Dedicated Host currently supports multiple instance types in an instance family, **Enabled** is selected for **Support multiple instance types**. To modify the host to support

a specific instance type, for **Support multiple instance types**, clear **Enable**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

Old console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions, Modify Supported Instance Types**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
 - If the Dedicated Host currently supports a specific instance type, **No** is selected for **Support multiple instance types**. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, select **Yes**.

You must first stop all instances running on the host before modifying it to support multiple instance types.

- If the Dedicated Host currently supports multiple instance types in an instance family, **Yes** is selected for **Support multiple instance types**, and **Instance family** displays the supported instance family. To modify the host to support a specific instance type, for **Support multiple instance types**, select **No**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the [modify-hosts](#) AWS CLI command.

The following command modifies a Dedicated Host to support multiple instance types within the **m5** instance family.

```
aws ec2 modify-hosts --instance-family m5 --host-ids h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support **m5.xlarge** instances only.

```
aws ec2 modify-hosts --instance-type m5.xlarge --instance-family --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the supported instance types for a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command.

The following command modifies a Dedicated Host to support multiple instance types within the **m5** instance family.

```
PS C:\> Edit-EC2Host --InstanceFamily m5 --HostId h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
PS C:\> Edit-EC2Host --InstanceType m5.xlarge --HostId h-012a3456b7890cdef
```

Modify instance tenancy and affinity

You can change the tenancy of an instance from dedicated to host, or from host to dedicated, after you have launched it. You can also modify the affinity between the instance and the host. To modify either instance tenancy or affinity, the instance must be in the stopped state.

Note

For T3 instances, you can't change the tenancy from dedicated to host, or from host to dedicated. Attempting to make one of these unsupported tenancy changes results in the `InvalidTenancy` error code.

You can modify an instance's tenancy and affinity using the following methods.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances**, and select the instance to modify.
3. Choose **Instance state, Stop**.
4. Open the context (right-click) menu on the instance and choose **Instance Settings, Modify Instance Placement**.
5. On the **Modify Instance Placement** page, configure the following:
 - **Tenancy**—Choose one of the following:
 - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see [Dedicated Instances \(p. 531\)](#).
 - Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.
 - **Affinity**—Choose one of the following:
 - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
 - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for **Target Host**.
 - **Target Host**—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

For more information, see [Understand auto-placement and affinity \(p. 509\)](#).

6. Choose **Save**.

AWS CLI

To modify instance tenancy or affinity

Use the `modify-instance-placement` AWS CLI command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
aws ec2 modify-instance-placement --instance-id i-1234567890abcdef0 --affinity host --  
host-id h-012a3456b7890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the [Edit-EC2InstancePlacement](#) AWS Tools for Windows PowerShell command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
PS C:\> Edit-EC2InstancePlacement -InstanceId i-1234567890abcdef0 -Affinity host -  
HostId h-012a3456b7890cdef
```

View Dedicated Hosts

You can view details about a Dedicated Host and the individual instances on it using the following methods.

New console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select a host.
4. For information about the host, choose **Details**.

Available vCPUs indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose **Running instances**.

Old console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select a host.
4. For information about the host, choose **Description**. **Available vCPUs** indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose **Instances**.

AWS CLI

To view the capacity of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command.

The following example uses the [describe-hosts](#) (AWS CLI) command to view the available instance capacity for a Dedicated Host that supports multiple instance types within the c5 instance family. The Dedicated Host already has two c5.4xlarge instances and four c5.2xlarge instances running on it.

```
$ aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

```
"AvailableInstanceCapacity": [  
    { "AvailableCapacity": 2,  
      "InstanceType": "c5.xlarge",  
      "TotalCapacity": 18 },  
    { "AvailableCapacity": 4,  
      "InstanceType": "c5.large",  
      "TotalCapacity": 36 }  
],  
"AvailableVCpus": 8
```

PowerShell

To view the instance capacity of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

Tag Dedicated Hosts

You can assign custom tags to your existing Dedicated Hosts to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host based on the custom tags that you assigned. Dedicated Host tags can also be used for cost allocation tracking.

You can also apply tags to Dedicated Hosts at the time of creation. For more information, see [Allocate Dedicated Hosts \(p. 504\)](#).

You can tag a Dedicated Host using the following methods.

New console

To tag a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host to tag, and then choose **Actions, Manage tags**.
4. In the **Manage tags** screen, choose **Add tag**, and then specify the key and value for the tag.
5. (Optional) Choose **Add tag** to add additional tags to the Dedicated Host.
6. Choose **Save changes**.

Old console

To tag a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host to tag, and then choose **Tags**.
4. Choose **Add/Edit Tags**.
5. In the **Add/Edit Tags** dialog box, choose **Create Tag**, and then specify the key and value for the tag.
6. (Optional) Choose **Create Tag** to add additional tags to the Dedicated Host.
7. Choose **Save**.

AWS CLI

To tag a Dedicated Host

Use the [create-tags](#) AWS CLI command.

The following command tags the specified Dedicated Host with `Owner=TeamA`.

```
aws ec2 create-tags --resources h-abc12345678909876 --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The `New-EC2Tag` command needs a `Tag` object, which specifies the key and value pair to be used for the Dedicated Host tag. The following commands create a `Tag` object named `$tag`, with a key and value pair of `Owner` and `TeamA` respectively.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

The following command tags the specified Dedicated Host with the `$tag` object.

```
PS C:\> New-EC2Tag -Resource h-abc12345678909876 -Tag $tag
```

Monitor Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Locate the Dedicated Host in the list and review the value in the **State** column.

AWS CLI

To view the state of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command and then review the state property in the hostSet response element.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

PowerShell

To view the state of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command and then review the state property in the hostSet response element.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

The following table explains the possible Dedicated Host states.

State	Description
available	AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.
released	The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.
under-assessment	AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.
pending	The Dedicated Host cannot be used for new instance launches. It is either being modified to support multiple instance types (p. 511) , or a host recovery (p. 526) is in progress.
permanent-failure	An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might continue to run. If you stop or terminate all instances on a Dedicated Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.
released-permanent-failure	AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.

Release Dedicated Hosts

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

You can release a Dedicated Host using the following methods.

New console

To release a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions, Release host**.
5. To confirm, choose **Release**.

Old console

To release a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions, Release Hosts**.
5. Choose **Release** to confirm.

AWS CLI

To release a Dedicated Host

Use the [release-hosts](#) AWS CLI command.

```
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

PowerShell

To release a Dedicated Host

Use the [Remove-EC2Hosts](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Remove-EC2Hosts -HostId h-012a3456b7890cdef
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to `released`, and you are not able to launch any instances onto that host.

Note

If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience `LimitExceeded` errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their host tenancy setting.

Purchase Dedicated Host Reservations

You can purchase reservations using the following methods:

Console

To purchase reservations

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. Choose **Dedicated Hosts, Dedicated Host Reservations, Purchase Dedicated Host Reservation**.
3. On the **Purchase Dedicated Host Reservation** screen, you can search for available offerings using the default settings, or you can specify custom values for the following:
 - **Host instance family**—The options listed correspond with the Dedicated Hosts in your account that are not already assigned to a reservation.
 - **Availability Zone**—The Availability Zone of the Dedicated Hosts in your account that aren't already assigned to a reservation.
 - **Payment option**—The payment option for the offering.
 - **Term**—The term of the reservation, which can be one or three years.
4. Choose **Find offering** and select an offering that matches your requirements.
5. Choose the Dedicated Hosts to associate with the reservation, and then choose **Review**.
6. Review your order and choose **Order**.

AWS CLI

To purchase reservations

1. Use the [describe-host-reservation-offerings](#) AWS CLI command to list the available offerings that match your needs. The following example lists the offerings that support instances in the `m4` instance family and have a one-year term.

Note

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
aws ec2 describe-host-reservation-offerings --filter Name=instance-family,Values=m4  
--max-duration 31536000
```

The command returns a list of offerings that match your criteria. Note the `offeringId` of the offering to purchase.

2. Use the [purchase-host-reservation](#) AWS CLI command to purchase the offering and provide the `offeringId` noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of `purpose` and a value of `production`.

```
aws ec2 purchase-host-reservation --offering-id hro-03f707bf363b6b324 --  
host-id-set h-013abcd2a00cbd123 --tag-specifications 'ResourceType=host-  
reservation,Tags=[{Key=purpose,Value=production}]'
```

PowerShell

To purchase reservations

1. Use the [Get-EC2HostReservationOffering](#) AWS Tools for Windows PowerShell command to list the available offerings that match your needs. The following examples list the offerings that support instances in the `m4` instance family and have a one-year term.

Note

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
PS C:\> $filter = @{Name="instance-family"; Value="m4"}
```

```
PS C:\> Get-EC2HostReservationOffering -filter $filter -MaxDuration 31536000
```

The command returns a list of offerings that match your criteria. Note the `offeringId` of the offering to purchase.

2. Use the `New-EC2HostReservation` AWS Tools for Windows PowerShell command to purchase the offering and provide the `offeringId` noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

```
PS C:\> New-EC2HostReservation -OfferingId hro-03f707bf363b6b324 -  
HostIdSet h-013abcd2a00cb123
```

View Dedicated Host reservations

You can view information about the Dedicated Hosts that are associated with your reservation, including:

- The term of the reservation
- The payment option
- The start and end dates

You can view details of your Dedicated Host reservations using the following methods.

Console

To view the details of a Dedicated Host reservation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, choose **Dedicated Host Reservations**, and then select the reservation from the list provided.
4. Choose **Details** for information about the reservation.
5. Choose **Hosts** for information about the Dedicated Hosts with which the reservation is associated.

AWS CLI

To view the details of a Dedicated Host reservation

Use the `describe-host-reservations` AWS CLI command.

```
aws ec2 describe-host-reservations
```

PowerShell

To view the details of a Dedicated Host reservation

Use the `Get-EC2HostReservation` AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2HostReservation
```

Tag Dedicated Host Reservations

You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host Reservation based on the custom tags that you assigned.

You can tag a Dedicated Host Reservation using the command line tools only.

AWS CLI

To tag a Dedicated Host Reservation

Use the [create-tags](#) AWS CLI command.

```
aws ec2 create-tags --resources hr-1234563a4ffc669ae --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host Reservation

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag parameter, which specifies the key and value pair to be used for the Dedicated Host Reservation tag. The following commands create the Tag parameter.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

```
PS C:\> New-EC2Tag -Resource hr-1234563a4ffc669ae -Tag $tag
```

Work with shared Dedicated Hosts

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (*owner*) shares it with other AWS accounts (*consumers*). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Prerequisites for sharing Dedicated Hosts

- To share a Dedicated Host, you must own it in your AWS account. You can't share a Dedicated Host that has been shared with you.
- To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Limitations for sharing Dedicated Hosts

You can't share Dedicated Hosts that have been allocated for the following instance types: `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`.

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID (AZ ID)*. The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an Availability Zone ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the Availability Zone IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.

2. The Availability Zone IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Dedicated Host

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

Important

Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.

To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

Note

After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

You can share a Dedicated Host that you own by using one of the following methods.

Amazon EC2 console

To share a Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to share and choose **Actions, Share host**.
4. Select the resource share to which to add the Dedicated Host and choose **Share host**.

It could take a few minutes for consumers to get access to the shared host.

AWS RAM console

To share a Dedicated Host that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

AWS CLI

To share a Dedicated Host that you own using the AWS CLI

Use the [create-resource-share](#) command.

Unshare a shared Dedicated Host

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:

- Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
- Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for [retirement](#). Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is reshared with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share. You can do this by using one of the following methods.

Amazon EC2 console

To unshare a shared Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to unshare and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose **Remove host from resource share**.

AWS RAM console

To unshare a shared Dedicated Host that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

Command line

To unshare a shared Dedicated Host that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify a shared Dedicated Host

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

Amazon EC2 console

To identify a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The **Owner** column shows the AWS account ID of the Dedicated Host owner.

Command line

To identify a shared Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you.

View instances running on a shared Dedicated Host

Owners and consumers can view the instances running on a shared Dedicated Host at any time using one of the following methods.

Amazon EC2 console

To view the instances running on a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to view the instances and choose **Instances**. The tab lists the instances that are running on the host. Owners see all of the instances running on the host, including instances launched by consumers. Consumers only see running instances that they launched onto the host. The **Owner** column shows the AWS account ID of the account that launched the instance.

Command line

To view the instances running on a shared Dedicated Host using the AWS CLI

Use the `describe-hosts` command. The command returns the instances running on each Dedicated Host. Owners see all of the instances running on the host. Consumers only see running instances that they launched on the shared hosts. `InstanceOwnerId` shows the AWS account ID of the instance owner.

Shared Dedicated Host permissions

Permissions for owners

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can't take any action on running instances that were launched by consumers.

Permissions for consumers

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can't modify the shared Dedicated Host in any way, and they can't view or modify instances that were launched by other consumers or the Dedicated Host owner.

Billing and metering

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.

Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see [Host recovery \(p. 526\)](#).

Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure concerning system power or network connectivity events. Other Dedicated Host issues will require manual intervention to recover from.

Host recovery basics

Dedicated Hosts and the host resource groups recovery process use host-level health checks to assess Dedicated Host availability and to detect underlying system failures. The type of Dedicated Host failure determines if Dedicated Host auto recovery is possible. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

Dedicated Host auto recovery

When a system power or network connectivity failure is detected on your Dedicated Host, Dedicated Host auto recovery is initiated and Amazon EC2 **automatically allocates a replacement Dedicated Host**. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings
- Reservation

When the replacement Dedicated Host is allocated, the **instances are recovered on to the replacement Dedicated Host**. The recovered instances retain the same attributes as the original instances, including:

- Instance ID

- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

Additionally, the built-in integration with AWS License Manager automates the tracking and management of your licenses.

Note

AWS License Manager integration is supported only in Regions in which AWS License Manager is available.

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.

When all of the instances have been recovered on to the replacement Dedicated Host, **the impaired Dedicated Host is released**, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Personal Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification (if notification settings have been configured for AWS License Manager). If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see [Using License Configurations](#) and [Settings in License Manager](#) in the *AWS License Manager User Guide*.

Scenarios without Dedicated Host auto recovery

Dedicated Host auto recovery does not occur when hardware or software issues impact the physical host and manual intervention is required. You will receive a retirement notification in the AWS Personal Health Dashboard, an Amazon CloudWatch event, and the AWS account owner email address receives a message regarding the Dedicated Host failure.

Stopped instances are not recovered on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.

Instances with instance storage are not recovered on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

Supported instance types

Host recovery is supported for the following instance families: A1, C3, C4, C5, C5n, C6g, C6i, Inf1, M3, M4, M5, M5n, M6g, M6i, P3, R3, R4, R5, R5n, R6g, R6i, X1, X1e, X2gd, u-6tb1, u-9tb1, u-12tb1, u-18tb1, and u-24tb1.

To recover instances that are not supported, see [Manually recover unsupported instances \(p. 529\)](#).

Note

Dedicated Host auto recovery of supported metal [instance types](#) will take longer to detect and recover from than non-metal instance types.

Configure host recovery

You can configure host recovery at the time of Dedicated Host allocation, or after allocation using the Amazon EC2 console or AWS Command Line Interface (CLI).

Contents

- [Enable host recovery \(p. 528\)](#)
- [Disable host recovery \(p. 528\)](#)
- [View the host recovery configuration \(p. 528\)](#)

Enable host recovery

You can enable host recovery at the time of Dedicated Host allocation or after allocation.

For more information about enabling host recovery at the time of Dedicated Host allocation, see [Allocate Dedicated Hosts \(p. 504\)](#).

To enable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to enable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Enable**, and then choose **Save**.

To enable host recovery after allocation using the AWS CLI

Use the `modify-hosts` command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery on --host-ids h-012a3456b7890cdef
```

Disable host recovery

You can disable host recovery at any time after the Dedicated Host has been allocated.

To disable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to disable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Disable**, and then choose **Save**.

To disable host recovery after allocation using the AWS CLI

Use the `modify-hosts` command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery off --host-ids h-012a3456b7890cdef
```

View the host recovery configuration

You can view the host recovery configuration for a Dedicated Host at any time.

To view the host recovery configuration for a Dedicated Host using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host Recovery** field.

To view the host recovery configuration for a Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command.

```
$ aws ec2 describe-hosts --host-ids h-012a3456b7890cdef
```

The `HostRecovery` response element indicates whether host recovery is enabled or disabled.

Host recovery states

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the `under-assessment` state, and all of the instances enter the `impaired` state. You can't launch instances on to the impaired Dedicated Host while it is in the `under-assessment` state.

After the replacement Dedicated Host is allocated, it enters the `pending` state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the `pending` state. Recovered instances on the replacement Dedicated Host remain in the `impaired` state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the `available` state, and the recovered instances return to the `running` state. You can launch instances on to the replacement Dedicated Host after it enters the `available` state. The original impaired Dedicated Host is permanently released and it enters the `released-permanent-failure` state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the `permanent-failure` state.

Manually recover unsupported instances

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.

Warning

Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

Manually recover EBS-backed instances

For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see [Stop and start your instance \(p. 637\)](#).

Manually recover instance store-backed instances

For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.

3. Terminate the original instance on the impaired Dedicated Host.

Related services

Dedicated Host integrates with the following services:

- **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

Pricing

There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the `available` state.

If the impaired Dedicated Host was billed using the `On-Demand` rate, the replacement Dedicated Host is also billed using the `On-Demand` rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Track configuration changes

You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When `On`, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.
- **Host recording status**—When `Enabled`, the configuration information for Dedicated Hosts is recorded.
- **Instance recording status**—When `Enabled`, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the `Edit Config Recording` button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three are enabled, the icon is green. To edit the settings, choose `Edit Config Recording`. You are directed to the `Set up AWS Config` page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see [Setting up AWS Config using the Console](#) in the *AWS Config Developer Guide*.

Note

AWS Config records your resources after it discovers them, which might take several minutes.

After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- By using the AWS Config console. For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see [Viewing Configuration Details in the AWS Config Console](#) in the *AWS Config Developer Guide*.
- By running AWS CLI commands. First, you can use the `list-discovered-resources` command to get a list of all hosts and instances. Then, you can use the `get-resource-config-history` command to get the configuration details of a host or instance for a specific time interval. For more information, see [View Configuration Details Using the CLI](#) in the *AWS Config Developer Guide*.
- By using the AWS Config API in your applications. First, you can use the `ListDiscoveredResources` action to get a list of all hosts and instances. Then, you can use the `GetResourceConfigHistory` action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.

```
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --  
resource-id i-1234567890abcdef0
```

To manage AWS Config settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Dedicated Hosts** page, choose **Edit Config Recording**.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see [Setting up AWS Config using the Console](#).

For more information, see [Viewing Configuration Details in the AWS Config Console](#).

Dedicated Instances

Dedicated Instances are Amazon EC2 instances that run in a virtual private cloud (VPC) on hardware that's dedicated to a single customer. Dedicated Instances that belong to different AWS accounts are physically isolated at a hardware level, even if those accounts are linked to a single payer account. However, Dedicated Instances might share hardware with other instances from the same AWS account that are not Dedicated Instances.

Note

A *Dedicated Host* is also a physical server that's dedicated for your use. With a Dedicated Host, you have visibility and control over how instances are placed on the server. For more information, see [Dedicated Hosts \(p. 498\)](#).

Dedicated Instance basics

Dedicated Instances can be launched into an Amazon VPC only.

When you launch an instance, the instance's tenancy attribute determines the hardware that it runs on. To launch a Dedicated Instance, you must specify an instance tenancy of dedicated.

Note

Instances with a tenancy value of default run on shared tenancy hardware. Instances with a tenancy value of host run on a Dedicated Host. For more information about working with Dedicated Hosts, see [Dedicated Hosts \(p. 498\)](#).

The tenancy of the VPC into which you launch the instance can also determine the instance's tenancy. A VPC can have a tenancy of either default or dedicated. If you launch an instance into a VPC that has a tenancy of default, the instance runs on shared tenancy hardware by default, unless you specify a different tenancy for the instance. If you launch an instance into a VPC that has a tenancy of dedicated, the instance runs as a Dedicated Instance by default, unless you specify a different tenancy for the instance.

To launch Dedicated Instances, you can do the following:

- Create a VPC with a tenancy of dedicated and launch all instances as Dedicated Instances by default. For more information, see [Create a VPC with an instance tenancy of dedicated \(p. 534\)](#).
- Create a VPC with a tenancy of default and manually specify a tenancy of dedicated for the instances that you want to run as Dedicated Instances. For more information, see [Launch Dedicated Instances into a VPC \(p. 535\)](#).

Supported features

Dedicated Instances support the following features and AWS service integrations:

Topics

- [Reserved Instances \(p. 532\)](#)
- [Automatic scaling \(p. 533\)](#)
- [Automatic recovery \(p. 533\)](#)
- [Dedicated Spot Instances \(p. 533\)](#)
- [Burstable performance instances \(p. 533\)](#)

Reserved Instances

To guarantee that sufficient capacity is available to launch Dedicated Instances, you can purchase Dedicated Reserved Instances. For more information, see [Reserved Instances \(p. 396\)](#).

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance into a VPC at a much reduced usage fee; the price break in the usage charge applies only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with default tenancy; it does not apply to a running instance with dedicated tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

Automatic scaling

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see [Launching Auto Scaling Instances in a VPC](#) in the *Amazon EC2 Auto Scaling User Guide*.

Automatic recovery

You can configure automatic recovery for a Dedicated Instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see [Recover your instance \(p. 667\)](#).

Dedicated Spot Instances

You can run a Dedicated Spot Instance by specifying a tenancy of dedicated when you create a Spot Instance request. For more information, see [Specify a tenancy for your Spot Instances \(p. 450\)](#).

Burstable performance instances

You can leverage the benefits of running on dedicated tenancy hardware with [the section called "Burstable performance instances" \(p. 266\)](#). T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see [the section called "Key concepts" \(p. 268\)](#).

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short-term variability if you launch multiple T3 Dedicated Instances that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

Differences between Dedicated Instances and Dedicated Hosts

Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto physical servers that are dedicated for your use.

There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some differences between the two. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores on the host	No visibility
Host and instance affinity	Allows you to consistently deploy your instances onto the same host over time	Not supported

	Dedicated Host	Dedicated Instance
Targeted instance placement	Provides control over how instances are placed on the host	Not supported
Automatic instance recovery	Supported	Supported
Bring Your Own License (BYOL)	Supported	Not supported

For more information about Dedicated Hosts, see [Dedicated Hosts \(p. 498\)](#).

Dedicated Instances limitations

Keep the following in mind when using Dedicated Instances:

- Some AWS services or their features are not supported with a VPC with the instance tenancy set to dedicated. Refer to the respective service's documentation to confirm if there are any limitations.
- Some instance types can't be launched into a VPC with the instance tenancy set to dedicated. For more information about supported instance types, see [Amazon EC2 Dedicated Instances](#).
- When you launch a Dedicated Instance backed by Amazon EBS, the EBS volume doesn't run on single-tenant hardware.

Pricing for Dedicated Instances

Pricing for Dedicated Instances is different from pricing for On-Demand Instances. For more information, see the [Amazon EC2 Dedicated Instances product page](#).

Work with Dedicated Instances

You can create a VPC with an instance tenancy of dedicated to ensure that all instances launched into the VPC are Dedicated Instances. Alternatively, you can specify the tenancy of the instance during launch.

Topics

Create a VPC with an instance tenancy of dedicated

When you create a VPC, you have the option of specifying its instance tenancy. If you're using the Amazon VPC console, you can create a VPC using the VPC wizard or the [Your VPCs](#) page.

If you launch an instance into a VPC that has an instance tenancy of dedicated, your instance is automatically a Dedicated Instance, regardless of the tenancy of the instance.

Console

To create a VPC with an instance tenancy of dedicated (VPC Wizard)

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. From the dashboard, choose **Launch VPC Wizard**.
3. Select a VPC configuration, and then choose **Select**.
4. For **Hardware tenancy**, choose **Dedicated**.
5. Choose **Create VPC**.

To create a VPC with an instance tenancy of dedicated (Create VPC dialog box)

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Your VPCs**, and then choose **Create VPC**.
3. For **Tenancy**, choose **Dedicated**. Specify the CIDR block, and choose **Create VPC**.

Command line

To set the tenancy option when you create a VPC using the command line

- [create-vpc](#) (AWS CLI)
- [New-EC2Vpc](#) (AWS Tools for Windows PowerShell)

Launch Dedicated Instances into a VPC

You can launch a Dedicated Instance using the Amazon EC2 launch instance wizard.

Console

To launch a Dedicated Instance into a default tenancy VPC using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI and choose **Select**.
4. On the **Choose an Instance Type** page, select the instance type and choose **Next: Configure Instance Details**.

Note

Ensure that you choose an instance type that's supported as a Dedicated Instance. For more information, see [Amazon EC2 Dedicated Instances](#).

5. On the **Configure Instance Details** page, select a VPC and subnet. For **Tenancy**, choose **Dedicated - Run a dedicated instance**, and then choose **Next: Add Storage**.
6. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch** to choose a key pair and launch the Dedicated Instance.

Command line

To set the tenancy option for an instance during launch using the command line

- [run-instances](#) (AWS CLI)

- [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

For more information about launching an instance with a tenancy of `host`, see [Launch instances onto a Dedicated Host \(p. 506\)](#).

Display tenancy information

Console

To display tenancy information for your VPC using the console

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Your VPCs**.
3. Check the instance tenancy of your VPC in the **Tenancy** column.
4. If the **Tenancy** column is not displayed, choose the settings icon () in the top-right corner, toggle to choose **Tenancy**, and choose **Confirm**.

To display tenancy information for your instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Check the tenancy of your instance in the **Tenancy** column.
4. If the **Tenancy** column is not displayed, do one of the following:
 - Choose the settings icon () in the top-right corner, toggle to choose **Tenancy**, and choose **Confirm**.
 - Select the instance. On the **Details** tab near the bottom of the page, under **Host and placement group**, check the value for **Tenancy**.

Command line

To describe the tenancy of your VPC using the command line

- [describe-vpcs](#) (AWS CLI)
- [Get-EC2Vpc](#) (AWS Tools for Windows PowerShell)

To describe the tenancy of your instance using the command line

- [describe-instances](#) (AWS CLI)
- [Get-EC2Instance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance offering using the command line

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (AWS Tools for Windows PowerShell)

Change the tenancy of an instance

You can change the tenancy of a stopped instance only from dedicated to host, or from host to dedicated after launch. The changes that you make take effect the next time the instance starts.

Note

- You can't change the tenancy of an instance from default to dedicated or host after launch. And you can't change the tenancy of an instance from dedicated or host to default after launch.
- For T3 instances, you can't change the tenancy from dedicated to host, or from host to dedicated. Attempting to make one of these unsupported tenancy changes results in the `InvalidTenancy` error code.

Console

To change the tenancy of an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select your instance.
3. Choose **Instance state, Stop instance, Stop**.
4. Choose **Actions, Instance settings, Modify instance placement**.
5. For **Tenancy**, choose whether to run your instance on dedicated hardware or on a Dedicated Host. Choose **Save**.

Command line

To modify the tenancy value of an instance using the command line

- [modify-instance-placement](#) (AWS CLI)
- [Edit-EC2InstancePlacement](#) (AWS Tools for Windows PowerShell)

Change the tenancy of a VPC

You can change the instance tenancy of a VPC from dedicated to default after you create it. Modifying the instance tenancy of the VPC does not affect the tenancy of any existing instances in the VPC. The next time you launch an instance in the VPC, it has a tenancy of default, unless you specify otherwise during launch.

Note

You cannot change the instance tenancy of a VPC from default to dedicated after it is created.

You can modify the instance tenancy of a VPC using the AWS CLI, an AWS SDK, or the Amazon EC2 API only.

Command line

To modify the instance tenancy attribute of a VPC using the AWS CLI

Use the [modify-vpc-tenancy](#) command and specify the ID of the VPC and instance tenancy value. The only supported value is `default`.

```
aws ec2 modify-vpc-tenancy --vpc-id vpc-1a2b3c4d --instance-tenancy default
```

On-Demand Capacity Reservations

On-Demand Capacity Reservations enable you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This gives you the ability to create and manage Capacity Reservations independently from the billing discounts offered by Savings Plans or Regional Reserved Instances.

By creating Capacity Reservations, you ensure that you always have access to EC2 capacity when you need it, for as long as you need it. You can create Capacity Reservations at any time, without entering into a one-year or three-year term commitment, and the capacity is available immediately. Billing starts as soon as the capacity is provisioned and the Capacity Reservation enters the active state. When you no longer need it, cancel the Capacity Reservation to stop incurring charges.

When you create a Capacity Reservation, you specify:

- The Availability Zone in which to reserve the capacity
- The number of instances for which to reserve capacity
- The instance attributes, including the instance type, tenancy, and platform/OS

Capacity Reservations can only be used by instances that match their attributes. By default, they are automatically used by running instances that match the attributes. If you don't have any running instances that match the attributes of the Capacity Reservation, it remains unused until you launch an instance with matching attributes.

In addition, you can use Savings Plans and Regional Reserved Instances with your Capacity Reservations to benefit from billing discounts. AWS automatically applies your discount when the attributes of a Capacity Reservation match the attributes of a Savings Plan or Regional Reserved Instance. For more information, see [Billing discounts \(p. 541\)](#).

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Term	No commitment required. Can be created and canceled as needed.	Requires a fixed one-year or three-year commitment		
Capacity benefit	Capacity reserved in a specific Availability Zone.		No capacity reserved.	
Billing discount	No billing discount. †	Provides a billing discount.		
Instance Limits	Your On-Demand Instance limits per Region apply.	Default is 20 per Availability Zone. You can request a limit increase.	Default is 20 per Region. You can request a limit increase.	No limit.

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- [Reserved Instances \(p. 396\)](#)
- [Savings Plans User Guide](#)

Supported platforms

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following platforms:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- RHEL with SQL Server Standard
- RHEL with SQL Server Enterprise
- RHEL with SQL Server Web
- RHEL with HA
- RHEL with HA and SQL Server Standard
- RHEL with HA and SQL Server Enterprise

When you purchase a Capacity Reservation, you must specify the *platform* that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, excluding BYOL, you must choose the specific platform. For example, the **SUSE Linux** or **Red Hat Enterprise Linux** platform.
- For all other Linux distributions (including Ubuntu), choose the **Linux/UNIX** platform.
- If you bring your existing RHEL subscription (BYOL), you must choose the **Linux/UNIX** platform.

For more information about the supported Windows platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Windows Instances*.

Quotas

The number of instances for which you are allowed to reserve capacity is based on your account's On-Demand Instance quota. You can reserve capacity for as many instances as that quota allows, minus the number of instances that are already running.

Limitations

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.
- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see [Work with shared Capacity Reservations \(p. 557\)](#).
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can be created in cluster placement groups. Spread and partition placement groups are not supported.
- Capacity Reservations can't be used with Dedicated Hosts.
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.

Capacity Reservation pricing and billing

The price for a Capacity Reservation varies by payment option.

Pricing

When the Capacity Reservation enters the active state, you are charged the equivalent On-Demand rate whether you run instances in the reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your EC2 bill. When you run an instance that matches the attributes of a reservation, you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 m4.1large Linux instances and run 15 m4.1large Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. For more information, see [Billing discounts \(p. 541\)](#).

For more information, see [Amazon EC2 Pricing](#).

Billing

Billing starts as soon as the capacity is provisioned and the Capacity Reservation enters the active state, and it continues while the Capacity Reservation remains in the active state.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a reservation remains active in your account for 24 hours and 15 minutes, you will be billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one m4.1large Linux instance, which has an On-Demand rate of \$0.10 per usage hour. In this example, the Capacity Reservation is active in the account for five hours. The Capacity Reservation is

unused for the first hour, so it is billed for one unused hour at the `m4.large` instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an `m4.large` instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the `m4.large` instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the `m4.large` instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the `m4.large` instance type.

Hour	1	2	3	4	5	6	Total cost
Unused Capacity Reservation	\$0.10	\$0.00	\$0.00	\$0.00	\$0.00	\$0.00	\$0.10
On-demand Instance Usage	\$0.00	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.50
Hourly cost	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.60

Billing discounts

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- [Reserved Instances \(p. 396\)](#)
- [Savings Plans User Guide](#)

Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details**, expand the **Elastic Compute Cloud** section and the Region to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see [Capacity Reservation Line Items](#) in the *AWS Billing and Cost Management User Guide*.

Work with Capacity Reservations

To start using Capacity Reservations, you create the capacity reservation in the required Availability Zone. Then, you can launch instances into the reserved capacity, view its capacity utilization in real time, and increase or decrease its capacity as needed.

By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, and Availability Zone). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This enables you to explicitly control which instances are allowed to run in that reserved capacity.

You can specify how the reservation ends. You can choose to cancel the Capacity Reservation or end it automatically at a specified time. If you specify an end time, the Capacity Reservation is canceled within an hour of the specified time. For example, if you specify 5/31/2019, 13:30:55, the Capacity Reservation is guaranteed to end between 13:30:55 and 14:30:55 on 5/31/2019. After a reservation ends, you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you cannot restart them.

until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation.

- [View a Capacity Reservation \(p. 546\)](#)
- [Cancel a Capacity Reservation \(p. 547\)](#)

Create a Capacity Reservation

After you create the Capacity Reservation, the capacity is available immediately. The capacity remains reserved for your use as long as the Capacity Reservation is active, and you can launch instances into it at any time. If the Capacity Reservation is open, new instances and existing instances that have matching attributes automatically run in the capacity of the Capacity Reservation. If the Capacity Reservation is targeted, instances must specifically target it to run in the reserved capacity.

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance limits \(p. 393\)](#).

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the Create a Capacity Reservation page, configure the following settings in the **Instance details** section. The instance type, platform, and Availability Zone of the instances that you launch must match the instance type, platform, and Availability Zone that you specify here or the Capacity Reservation is not applied. For example, if an open Capacity Reservation doesn't match, an instance launch that targets that Capacity Reservation explicitly will fail.
 - a. **Instance Type**—The type of instance to launch into the reserved capacity.
 - b. **Launch EBS-optimized instances**—Specify whether to reserve the capacity for EBS-optimized instances. This option is selected by default for some instance types. For more information about EBS-optimized instances, see [Amazon Elastic Block Store \(p. 1347\)](#).
 - c. **Attach instance store at launch**—Specify whether instances launched into the Capacity Reservation use temporary block-level storage. The data on an instance store volume persists only during the life of the associated instance.
 - d. **Platform**—The operating system for your instances. For more information, see [Supported platforms \(p. 539\)](#). For more information about the supported Windows platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Windows Instances*.
 - e. **Availability Zone**—The Availability Zone in which to reserve the capacity.
 - f. **Tenancy**—Specify whether to run on shared hardware (default) or a dedicated instance.
 - g. **(Optional) Placement group ARN**—The ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Capacity Reservations in cluster placement groups \(p. 551\)](#).

- h. **Quantity**—The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the request is denied.
4. Configure the following settings in the **Reservation details** section:
 - a. **Reservation Ends**—Choose one of the following options:
 - **Manually**—Reserve the capacity until you explicitly cancel it.
 - **Specific time**—Cancel the capacity reservation automatically at the specified date and time.
 - b. **Instance eligibility**—Choose one of the following options:
 - **open**—(Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, and Availability Zone). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
 - **targeted**—The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, and Availability Zone), and that explicitly target the reservation.
 5. Choose **Request reservation**.

To create a Capacity Reservation using the AWS CLI

Use the [create-capacity-reservation](#) command. For more information, see [Supported platforms \(p. 539\)](#). For more information about the supported Windows platforms, see [Supported platforms in the Amazon EC2 User Guide for Windows Instances](#).

For example, the following command creates a Capacity Reservation that reserves capacity for three `m5.2xlarge` instances running Red Hat Enterprise Linux AMIs in the `us-east-1a` Availability Zone.

```
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Red Hat Enterprise Linux --availability-zone us-east-1a --instance-count 3
```

Launch instances into an existing Capacity Reservation

When you launch an instance, you can specify whether to launch the instance into any open Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations. You can only launch an instance into a Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and sufficient capacity. Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an open Capacity Reservation that has matching attributes and available capacity.

Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.

To launch instances into an existing Capacity Reservation using the console

1. Open the Launch Instance wizard by choosing **Launch Instances** from **Dashboard** or **Instances**.
2. Select an Amazon Machine Image (AMI) and an instance type.
3. Complete the **Configure Instance Details** page. For **Capacity Reservation**, choose one of the following options:
 - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
 - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.

- **Target by ID** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
 - **Target by group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.
4. Complete the remaining steps to launch the instances.

To launch an instance into an existing Capacity Reservation using the AWS CLI

Use the `run-instances` command and specify the `--capacity-reservation-specification` parameter.

The following example launches a `t2.micro` instance into any open Capacity Reservation that has matching attributes and available capacity:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationPreference=open
```

The following example launches a `t2.micro` instance into a targeted Capacity Reservation:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

The following example launches a `t2.micro` instance into a Capacity Reservation group:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

Modify a Capacity Reservation

You can change the attributes of an active Capacity Reservation after you have created it. You cannot modify a Capacity Reservation after it has expired or after you have explicitly canceled it.

When modifying a Capacity Reservation, you can only increase or decrease the quantity and change the way in which it is released. You cannot change the instance type, EBS optimization, instance store settings, platform, Availability Zone, or instance eligibility of a Capacity Reservation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.

If you specify a new quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

To modify a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.
3. Modify the **Quantity** or **Reservation ends** options as needed, and choose **Save changes**.

To modify a Capacity Reservation using the AWS CLI

Use the [modify-capacity-reservations](#) command:

For example, the following command modifies a Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0 --  
instance-count 8
```

Modify an instance's Capacity Reservation settings

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

To modify an instance's Capacity Reservation settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances** and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose **Actions, Modify Capacity Reservation Settings**.
4. For **Capacity Reservation**, choose one of the following options:
 - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
 - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
 - **Specify Capacity Reservation** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
 - **Specify Capacity Reservation group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

To modify an instance's Capacity Reservation settings using the AWS CLI

Use the [modify-instance-capacity-reservation-attributes](#) command.

For example, the following command changes an instance's Capacity Reservation setting to open or none.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0  
--capacity-reservation-specification CapacityReservationPreference=none|open
```

For example, the following command modifies an instance to target a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-  
id i-1234567890abcdef0 --capacity-reservation-specification  
CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

For example, the following command modifies an instance to target a specific Capacity Reservation group.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

View a Capacity Reservation

Capacity Reservations have the following possible states:

- **active**—The capacity is available for use.
 - **expired**—The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
 - **cancelled**—The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.
 - **pending**—The Capacity Reservation request was successful but the capacity provisioning is still pending.
 - **failed**—The Capacity Reservation request has failed. A request can fail due to request parameters that are not valid, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.

To view your Capacity Reservations using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 2. Choose **Capacity Reservations** and select a Capacity Reservation to view.
 3. Choose **View launched instances for this reservation**.

To view your Capacity Reservations using the AWS CLI

Use the `describe-capacity-reservations` command:

For example, the following command describes all Capacity Reservations.

```
aws ec2 describe-capacity-reservations
```

Example output.

```
        "PlacementGroupArn": "arn:aws:ec2:us-east-1:123456789012:placement-group/MyPG"
    },
    {
        "CapacityReservationId": "cr-abcdEXAMPLE9876ef",
        "EndDateType": "unlimited",
        "AvailabilityZone": "eu-west-1a",
        "InstanceMatchCriteria": "open",
        "Tags": [],
        "EphemeralStorage": false,
        "CreateDate": "2019-08-07T11:34:19.000Z",
        "AvailableInstanceCount": 3,
        "InstancePlatform": "Linux/UNIX",
        "TotalInstanceCount": 3,
        "State": "cancelled",
        "Tenancy": "default",
        "EbsOptimized": true,
        "InstanceType": "m5.large"
    }
]
```

Cancel a Capacity Reservation

You can cancel a Capacity Reservation at any time if you no longer need the reserved capacity. When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.

You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plan or Regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see [Modify an instance's Capacity Reservation settings \(p. 545\)](#).

To cancel a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations** and select the Capacity Reservation to cancel.
3. Choose **Cancel reservation, Cancel reservation**.

To cancel a Capacity Reservation using the AWS CLI

Use the `cancel-capacity-reservation` command:

For example, the following command cancels a Capacity Reservation with an ID of `cr-1234567890abcdef0`.

```
aws ec2 cancel-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0
```

Work with Capacity Reservation groups

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called *resource groups*. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. For more information about resource groups, see [What are resource groups?](#) in the *AWS Resource Groups User Guide*.

You can include multiple Capacity Reservations that have different attributes (instance type, platform, and Availability Zone) in a single resource group.

When you create resource groups for your Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, and Availability Zone) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation. To do this, set **Instance eligibility to targeted** (old console) or **Only instances that specify this reservation** (new console) when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

To create a group for your Capacity Reservations

Use the [create-group](#) AWS CLI command. For name, provide a descriptive name for the group, and for configuration, specify two Type request parameters:

- `AWS::EC2::CapacityReservationPool` to ensure that the resource group can be targeted for instance launches
- `AWS::ResourceGroups::Generic` with `allowed-resource-types` set to `AWS::EC2::CapacityReservation` to ensure that the resource group accepts Capacity Reservations only

For example, the following command creates a group named `MyCRGroup`.

```
$ aws resource-groups create-group --name MyCRGroup --configuration
'{"Type":"AWS::EC2::CapacityReservationPool"}' '{"Type":"AWS::ResourceGroups::Generic",
"Parameters": [{"Name": "allowed-resource-types", "Values":
["AWS::EC2::CapacityReservation"]}]}'
```

The following shows example output.

```
{  
    "GroupConfiguration": {  
        "Status": "UPDATE_COMPLETE",  
        "Configuration": [  
            {  
                "Type": "AWS::EC2::CapacityReservationPool"  
            },  
            {  
                "Type": "AWS::ResourceGroups::Generic",  
                "Parameters": [  
                    {  
                        "Values": [  
                            "AWS::EC2::CapacityReservation"  
                        ]  
                    }  
                ]  
            }  
        ]  
    }  
}
```

```
        ],
        "Name": "allowed-resource-types"
    }
}
],
"Group": {
    "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
    "Name": "MyCRGroup"
}
}
```

To add a Capacity Reservation to a group

Use the [group-resources](#) AWS CLI command. For `group`, specify the name of the group to which to add the Capacity Reservations, and for `resources`, specify ARNs of the Capacity Reservations to add. To add multiple Capacity Reservations, separate the ARNs with a space. To get the ARNs of the Capacity Reservations to add, use the [describe-capacity-reservations](#) AWS CLI command and specify the IDs of the Capacity Reservations.

For example, the following command adds two Capacity Reservations to a group named `MyCRGroup`.

```
$ aws resource-groups group-resources --group MyCRGroup --resource-arns arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1 arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

The following shows example output.

```
{
    "Failed": [],
    "Succeeded": [
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1",
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"
    ]
}
```

To view the Capacity Reservations in a specific group

Use the [list-group-resources](#) AWS CLI command. For `group`, specify the name of the group.

For example, the following command lists the Capacity Reservations in a group named `MyCRGroup`.

```
$ aws resource-groups list-group-resources --group MyCRGroup
```

The following shows example output.

```
{
    "QueryErrors": [],
    "ResourceIdentifiers": [
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1"
        },
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"
        }
    ]
}
```

```
    ]  
}
```

To view the groups to which a specific Capacity Reservation has been added (AWS CLI)

Use the [get-groups-for-capacity-reservation](#) AWS CLI command.

For example, the following command lists the groups to which Capacity Reservation cr-1234567890abcdef1 has been added.

```
$ aws ec2 get-groups-for-capacity-reservation --capacity-reservation-id cr-1234567890abcdef1
```

The following shows example output.

```
{  
    "CapacityReservationGroups": [  
        {  
            "OwnerId": "123456789012",  
            "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup"  
        }  
    ]  
}
```

To view the groups to which a specific Capacity Reservation has been added (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**, select the Capacity Reservation to view, and then choose **View**.

The groups to which the Capacity Reservation has been added are listed in the **Groups** card.

To remove a Capacity Reservation from a group

Use the [ungroup-resources](#) AWS CLI command. For **group**, specify the ARN of the group from which to remove the Capacity Reservation, and for **resources** specify the ARNs of the Capacity Reservations to remove. To remove multiple Capacity Reservations, separate the ARNs with a space.

The following example removes two Capacity Reservations from a group named MyCRGroup.

```
$ aws resource-groups ungroup-resources --group MyCRGroup --resource-arns arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

The following shows example output.

```
{  
    "Failed": [],  
    "Succeeded": [  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd",  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"  
    ]  
}
```

To delete a group

Use the [delete-group](#) AWS CLI command. For **group**, provide the name of the group to delete.

For example, the following command deletes a group named `MyCRGroup`.

```
$ aws resource-groups delete-group --group MyCRGroup
```

The following shows example output.

```
{  
    "Group": {  
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",  
        "Name": "MyCRGroup"  
    }  
}
```

Capacity Reservations in cluster placement groups

You can create Capacity Reservations in a cluster placement group to reserve Amazon EC2 compute capacity for your workloads. Cluster placement groups offer the benefit of low network latency and high network throughput.

Creating a Capacity Reservation in a cluster placement group ensures that you have access to compute capacity in your cluster placement groups when you need it, for as long as you need it. This is ideal for reserving capacity for high-performance (HPC) workloads that require compute scaling. It allows you to scale your cluster down while ensuring that the capacity remains available for your use so that you can scale back up when needed.

Topics

- [Limitations \(p. 551\)](#)
- [Work with Capacity Reservations in cluster placement groups \(p. 551\)](#)

Limitations

Keep the following in mind when creating Capacity Reservations in cluster placement groups:

- You can't modify an existing Capacity Reservation that is not in a placement group to reserve capacity in a placement group. To reserve capacity in a placement group, you must create the Capacity Reservation in the placement group.
- After you create a Capacity Reservation in a placement group, you can't modify it to reserve capacity outside of the placement group.
- You can increase your reserved capacity in a placement group by modifying an existing Capacity Reservation in the placement group, or by creating additional Capacity Reservations in the placement group. However, you increase your chances of getting an insufficient capacity error.
- You can't share Capacity Reservations that have been created in a cluster placement group.
- You can't delete a cluster placement group that has active Capacity Reservations. You must cancel all Capacity Reservations in the cluster placement group before you can delete it.

Work with Capacity Reservations in cluster placement groups

To start using Capacity Reservations with cluster placement groups, perform the following steps.

Note

If you want to create a Capacity Reservation in an existing cluster placement group, skip Step 1. Then for Steps 2 and 3, specify the ARN of the existing cluster placement group. For more information about how to find the ARN of your existing cluster placement group, see [Describe a placement group \(p. 1201\)](#).

Topics

- [Step 1: \(Conditional\) Create a cluster placement group for use with a Capacity Reservation \(p. 552\)](#)
- [Step 2: Create a Capacity Reservation in a cluster placement group \(p. 552\)](#)
- [Step 3: Launch instances into the cluster placement group \(p. 554\)](#)

Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation

Perform this step only if you need to create a new cluster placement group. To use an existing cluster placement group, skip this step and then for Steps 2 and 3, use the ARN of that cluster placement group. For more information about how to find the ARN of your existing cluster placement group, see [Describe a placement group \(p. 1201\)](#).

You can create the cluster placement group using one of the following methods.

Console

To create a cluster placement group using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Placement Groups**, and then choose **Create placement group**.
3. For **Name**, specify a descriptive name for the placement group.
4. For **Placement strategy**, choose **Cluster**.
5. Choose **Create group**.
6. Find the ARN of the cluster placement group that you created.

```
$ aws ec2 describe-placement-groups --group-names placement_group_name
```

Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

AWS CLI

To create a cluster placement group using the AWS CLI

Use the `create-placement-group` command. For `--group-name`, specify a descriptive name for the placement group, and for `--strategy`, specify `cluster`.

The following example creates a placement group named `MyPG` that uses the `cluster` placement strategy.

```
$ aws ec2 create-placement-group \
--group-name MyPG \
--strategy cluster
```

Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

Step 2: Create a Capacity Reservation in a cluster placement group

You create a Capacity Reservation in a cluster placement group in the same way that you create any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Create a Capacity Reservation \(p. 542\)](#).

Considerations

- The specified cluster placement group must be in the available state. If the cluster placement group is in the pending, deleting, or deleted state, the request fails.
- The Capacity Reservation and the cluster placement group must be in the same Availability Zone. If the request to create the Capacity Reservation specifies an Availability Zone that is different from that of the cluster placement group, the request fails.
- You can create Capacity Reservations only for instance types that are supported by cluster placement groups. If you specify an unsupported instance type, the request fails. For more information, see [Cluster placement group rules and limitations \(p. 1194\)](#).
- If you create an open Capacity Reservation in a cluster placement group and there are existing running instances that have matching attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy), those instances automatically run in the Capacity Reservation.
- Your request to create a Capacity Reservation could fail if one of the following is true:
 - Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your workload is flexible across instance types and sizes, try different instance attributes.
 - The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance limits \(p. 393\)](#).

You can create the Capacity Reservation in the cluster placement group using one of the following methods.

Console

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the Create a Capacity Reservation page, configure the instance type, platform, Availability Zone, Tenancy, quantity, and end date as needed.
4. For **Placement group ARN**, specify the ARN of the cluster placement group in which to create the Capacity Reservation.
5. Choose **Create**.

For more information, see [Create a Capacity Reservation \(p. 542\)](#).

AWS CLI

To create a Capacity Reservation using the AWS CLI

Use the `create-capacity-reservation` command. For `--placement-group-arn`, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
$ aws ec2 create-capacity-reservation \
--instance-type instance_type \
--instance-platform platform \
--availability-zone az \
--instance-count quantity \
--placement-group-arn placement_group_ARN
```

For more information, see [Create a Capacity Reservation \(p. 542\)](#).

Step 3: Launch instances into the cluster placement group

You launch an instance into a Capacity Reservation in a cluster placement group in the same way that you launch an instance into any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to launch the instance. For more information, see [Create a Capacity Reservation \(p. 543\)](#).

Considerations

- If the Capacity Reservation is open, you do not need to specify the Capacity Reservation in the instance launch request. If the instance has attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy) that match a Capacity Reservation in the specified placement group, the instance automatically runs in the Capacity Reservation.
- If the Capacity Reservation accepts only targeted instance launches, you must specify the target Capacity Reservation in addition to the cluster placement group in the request.
- If the Capacity Reservation is in a Capacity Reservation group, you must specify the target Capacity Reservation group in addition to the cluster placement group in the request. For more information, see [Work with Capacity Reservation groups \(p. 547\)](#).

You can launch an instance into a Capacity Reservation in a cluster placement group using one of the following methods.

Console

To launch instances into an existing Capacity Reservation using the console

1. Open the Launch Instance wizard by choosing **Launch Instances** from the **Dashboard** or from the **Instances** screen.
2. Select an Amazon Machine Image (AMI) and an instance type.
3. Complete the **Configure Instance Details** page:
 - a. For **Placement group**, select **Add instance to placement group**, choose **Add to existing placement group**, and then select the cluster placement group in which to launch the instance.
 - b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:
 - **Open** — To launch the instances into any open Capacity Reservation in the cluster placement group that has matching attributes and sufficient capacity.
 - **Target by ID** — To launch the instances into a Capacity Reservation that accepts only targeted instance launches.
 - **Target by group** — To launch the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group.
4. Complete the remaining steps to launch the instances.

For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).

AWS CLI

To launch instances into an existing Capacity Reservation using the AWS CLI

Use the `run-instances` command. If you need to target a specific Capacity Reservation or a Capacity Reservation group, specify the `--capacity-reservation-specification` parameter. For `--placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

The following command launches an instance into a targeted Capacity Reservation in a cluster placement group.

```
$ aws ec2 run-instances \
--image-id ami_id \
--count quantity \
--instance-type instance_type \
--key-name key_pair_name \
--subnet-id subnetid \
--capacity-reservation-specification
  CapacityReservationTarget={CapacityReservationId=capacity_reservation_id} \
--placement "GroupName=cluster_placement_group_name"
```

For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).

Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.

By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see [AWS Local Zones FAQs](#).

Considerations

You can't use Capacity Reservation groups in a Local Zone.

To use a Capacity Reservation in a Local Zone

1. Enable the Local Zone for use in your AWS account. For more information, see [Opt in to Local Zones \(p. 1033\)](#).
2. Create a Capacity Reservation in the Local Zone. For **Availability Zone**, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a. For more information, see [Create a Capacity Reservation \(p. 542\)](#).
3. Create a subnet in the Local Zone. For **Availability Zone**, choose the Local Zone. For more information, see [Creating a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Local Zone (for example subnet-123abc | us-west-2-lax-1a), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Local Zone. For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).

Capacity Reservations in Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run

applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see [AWS Wavelength Zones](#).

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-east-1-wl1-bos-wlz-1`.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Developer Guide*.

Considerations

You can't use Capacity Reservation groups in a Wavelength Zone.

To use a Capacity Reservation in a Wavelength Zone

1. Enable the Wavelength Zone for use in your AWS account. For more information, see [Enable Wavelength Zones](#) in the *Amazon EC2 User Guide for Linux Instances*.
2. Create a Capacity Reservation in the Wavelength Zone. For **Availability Zone**, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-east-1-wl1-bos-wlz-1`. For more information, see [Create a Capacity Reservation](#) (p. 542).
3. Create a subnet in the Wavelength Zone. For **Availability Zone**, choose the Wavelength Zone. For more information, see [Creating a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Wavelength Zone (for example `subnet-123abc | us-east-1-wl1-bos-wlz-1`), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Wavelength. For more information, see [Launch instances into an existing Capacity Reservation](#) (p. 543).

Capacity Reservations on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see [Work with shared Capacity Reservations](#) (p. 557).

Prerequisite

You must have an Outpost installed at your site. For more information, see [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

Considerations

- You can't use Capacity Reservation groups on an Outpost.

To use a Capacity Reservation on an Outpost

1. Create a subnet on the Outpost. For more information, see [Create a subnet](#) in the *AWS Outposts User Guide*.
2. Create a Capacity Reservation on the Outpost.
 - a. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
 - b. In the navigation pane, choose **Outposts**, and then choose **Actions**, **Create Capacity Reservation**.
 - c. Configure the Capacity Reservation as needed and then choose **Create**. For more information, see [Create a Capacity Reservation \(p. 542\)](#).

Note

The **Instance Type** drop-down lists only instance types that are supported by the selected Outpost, and the **Availability Zone** drop-down lists only the Availability Zone with which the selected Outpost is associated.

3. Launch an instance into the Capacity Reservation. For **Subnet** choose the subnet that you created in Step 1, and for **Capacity Reservation**, select the Capacity Reservation that you created in Step 2. For more information, see [Launch an instance on the Outpost](#) in the *AWS Outposts User Guide*.

Work with shared Capacity Reservations

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.

A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.
- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the AZ IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.
2. The AZ IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the `CapacityReservationPreference` parameter set to `open`, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
- If consumers launch instances that have matching attributes (instance type, platform, and Availability Zone) and have the `CapacityReservationPreference` parameter set to `open`, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources

to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the [AWS RAM console](#).

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Capacity Reservation. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

You can share a Capacity Reservation that you own using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To share a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Choose the Capacity Reservation to share and choose **Actions, Share reservation**.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

It could take a few minutes for consumers to get access to the shared Capacity Reservation.

To share a Capacity Reservation that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

To share a Capacity Reservation that you own using the AWS CLI

Use the `create-resource-share` command.

Stop sharing a Capacity Reservation

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:

- Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability.
- Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share. You can do this using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To stop sharing a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

To stop sharing a Capacity Reservation that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

To stop sharing a Capacity Reservation that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify a shared Capacity Reservation

Owners and consumers can identify shared Capacity Reservations using the Amazon EC2 console and AWS CLI

To identify a shared Capacity Reservation using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**. The screen lists Capacity Reservations that you own and Capacity Reservations that are shared with you. The **Owner** column shows the AWS account ID of the Capacity Reservation owner. (`me`) next to the AWS account ID indicates that you are the owner.

To identify a shared Capacity Reservation using the AWS CLI

Use the [describe-capacity-reservations](#) command. The command returns the Capacity Reservations that you own and Capacity Reservations that are shared with you. `OwnerId` shows the AWS account ID of the Capacity Reservation owner.

View shared Capacity Reservation usage

The owner of a shared Capacity Reservation can view its usage at any time using the Amazon EC2 console and the AWS CLI.

To view Capacity Reservation usage using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation for which to view the usage and choose the **Usage** tab.

The **AWS account ID** column shows the account IDs of the consumers currently using the Capacity Reservation. The **Launched instances** column shows the number of instances each consumer currently has running in the reserved capacity.

To view Capacity Reservation usage using the AWS CLI

Use the [get-capacity-reservation-usage](#) command. `AccountId` shows the account ID of the account using the Capacity Reservation. `UsedInstanceCount` shows the number of instances the consumer currently has running in the reserved capacity.

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

The Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity. Consumers are billed for the instances that they run inside the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

Capacity Reservation Fleets

An *On-Demand Capacity Reservation Fleet* is a group of Capacity Reservations.

A Capacity Reservation Fleet request contains all of the configuration information that's needed to launch a Capacity Reservation Fleet. Using a single request, you can reserve large amounts of Amazon EC2 capacity for your workload across multiple instance types, up to a target capacity that you specify.

After you create a Capacity Reservation Fleet, you can manage the Capacity Reservations in the fleet collectively by modifying or canceling the Capacity Reservation Fleet.

How Capacity Reservation Fleets work

When you create a Capacity Reservation Fleet, the Fleet attempts to create individual Capacity Reservations to meet the total target capacity that you specified in the Fleet request.

The number of instances for which the Fleet reserves capacity depends on the [*total target capacity \(p. 562\)*](#) and the [*instance type weights \(p. 563\)*](#) that you specify. The instance type for which it reserves capacity depends on the [*allocation strategy \(p. 563\)*](#) and [*instance type priorities \(p. 564\)*](#) that you use.

If there is insufficient capacity at the time the Fleet is created, and it is unable to immediately meet its total target capacity, the Fleet asynchronously attempts to create Capacity Reservations until it has reserved the requested amount of capacity.

When the Fleet reaches its total target capacity, it attempts to maintain that capacity. If a Capacity Reservation in the Fleet is cancelled, the Fleet automatically creates one or more Capacity Reservations, depending on your Fleet configuration, to replace the lost capacity and to maintain its total target capacity.

The Capacity Reservations in the Fleet can't be managed individually. They must be managed collectively by modifying the Fleet. When you modify a Fleet, the Capacity Reservations in the Fleet are automatically updated to reflect the changes.

Currently, Capacity Reservation Fleets support the open instance matching criteria, and all Capacity Reservations launched by a Fleet automatically use this instance matching criteria. With this criteria, new instances and existing instances that have matching attributes (instance type, platform, and Availability Zone) automatically run in the Capacity Reservations created by a Fleet. Capacity Reservation Fleets do not support target instance matching criteria.

Considerations

Keep the following in mind when working with Capacity Reservation Fleets:

- A Capacity Reservation Fleet can be created, modified, viewed, and cancelled using the AWS CLI and AWS API.
- The Capacity Reservations in a Fleet can't be managed individually. They must be managed collectively by modifying or cancelling the Fleet.
- A Capacity Reservation Fleet can't span across Regions.
- A Capacity Reservation Fleet can't span across Availability Zones.
- Capacity Reservations created by a Capacity Reservation Fleet are automatically tagged with the following AWS generated tag:
 - Key — aws:ec2-capacity-reservation-fleet
 - Value — *fleet_id*

You can use this tag to identify Capacity Reservations that were created by a Capacity Reservation Fleet.

Pricing

There are no additional charges for using Capacity Reservation Fleets. You are billed for the individual Capacity Reservations that are created by your Capacity Reservation Fleets. For more information about how Capacity Reservations are billed, see [Capacity Reservation pricing and billing \(p. 540\)](#).

Capacity Reservation Fleet concepts

This topic describes some of the concepts of Capacity Reservation Fleets.

Topics

- [Total target capacity \(p. 562\)](#)
- [Allocation strategy \(p. 563\)](#)
- [Instance type weight \(p. 563\)](#)
- [Instance type priority \(p. 564\)](#)

Total target capacity

The *total target capacity* defines the total amount of compute capacity that the Capacity Reservation Fleet reserves. You specify the total target capacity when you create the Capacity Reservation Fleet. After the Fleet has been created, Amazon EC2 automatically creates Capacity Reservations to reserve capacity up to the total target capacity.

The number of instances for which the Capacity Reservation Fleet reserves capacity is determined by the total target capacity and the *instance type weight* that you specify for each instance type in the Capacity Reservation Fleet ($\text{total target capacity}/\text{instance type weight}=\text{number of instances}$).

You can assign a total target capacity based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign the total target capacity based on the number of vCPUs required. If your workload requires 2048 vCPUs, specify a total target capacity of 2048 and then assign instance type weights based on the number of vCPUs provided by the instance types in the Fleet. For an example, see [Instance type weight \(p. 563\)](#).

Allocation strategy

The allocation strategy for your Capacity Reservation Fleet determines how it fulfills your request for reserved capacity from the instance type specifications in the Capacity Reservation Fleet configuration.

Currently, only the prioritized allocation strategy is supported. With this strategy, the Capacity Reservation Fleet creates Capacity Reservations using the priorities that you have assigned to each of the instance type specifications in the Capacity Reservation Fleet configuration. Lower priority values indicate higher priority for use. For example, say you create a Capacity Reservation Fleet that uses the following instance types and priorities:

- m4.16xlarge — priority = 1
- m5.16xlarge — priority = 3
- m5.24xlarge — priority = 2

The Fleet first attempts to create Capacity Reservations for m4.16xlarge. If Amazon EC2 has insufficient m4.16xlarge capacity, the Fleet attempts to create Capacity Reservations for m5.24xlarge. If Amazon EC2 has insufficient m5.24xlarge capacity, the Fleet creates Capacity Reservations for m5.16xlarge.

Instance type weight

The *instance type weight* is a weight that you assign to each instance type in the Capacity Reservation Fleet. The weight determines how many units of capacity each instance of that specific instance type counts toward the Fleet's *total target capacity*.

You can assign weights based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign weights based on the number of vCPUs provided by each instance type in the Capacity Reservation Fleet. In this case, if you create a Capacity Reservation Fleet using m4.16xlarge and m5.24xlarge instances, you would assign weights that correspond to the number of vCPUs for each instance as follows:

- m4.16xlarge — 64 vCPUs, weight = 64 units
- m5.24xlarge — 96 vCPUs, weight = 96 units

The instance type weight determines the number of instances for which the Capacity Reservation Fleet reserves capacity. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types and weights in the preceding example, the Fleet could reserve capacity for 6 m4.16xlarge instances (384 total target capacity/64 instance type weight=6 instances), or 4 m5.24xlarge instances (384 / 96 = 4).

If you do not assign instance type weights, or if you assign an instance type weight of 1, the total target capacity is based purely on instance count. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types in the preceding example, but omits the weights or specifies a weight of 1 for both instance types, the Fleet could reserve capacity for either 384 m4.16xlarge instances or 384 m5.24xlarge instances.

Instance type priority

The *instance type priority* is a value that you assign to the instance types in the Fleet. The priorities are used to determine which of the instance types specified for the Fleet should be prioritized for use.

Lower priority values indicate a higher priority for use.

Work with Capacity Reservation Fleets

Topics

- [Before you begin \(p. 564\)](#)
- [Capacity Reservation Fleet states \(p. 564\)](#)
- [Create a Capacity Reservation Fleet \(p. 565\)](#)
- [View a Capacity Reservation Fleet \(p. 566\)](#)
- [Modify a Capacity Reservation Fleet \(p. 568\)](#)
- [Cancel a Capacity Reservation Fleet \(p. 569\)](#)

Before you begin

Before you create a Capacity Reservation Fleet:

1. Determine the amount of compute capacity that is needed by your workload.
2. Decide on the instance types and Availability Zones that you want to use.
3. Assign each instance type a priority based on your needs and preferences. For more information, see [Instance type priority \(p. 564\)](#).
4. Create a capacity weighting system that makes sense for your workload. Assign a weight to each instance type and determine your total target capacity. For more information, see [Instance type weight \(p. 563\)](#) and [Total target capacity \(p. 562\)](#).
5. Determine whether you need the Capacity Reservation indefinitely or only for a specific period of time.

Capacity Reservation Fleet states

A Capacity Reservation Fleet can be in one of the following states:

- **submitted** — The Capacity Reservation Fleet request has been submitted and Amazon EC2 is preparing to create the Capacity Reservations.
- **modifying** — The Capacity Reservation Fleet is being modified. The Fleet remains in this state until the modification is complete.
- **active** — The Capacity Reservation Fleet has fulfilled its total target capacity and it is attempting to maintain this capacity. The Fleet remains in this state until it is modified or deleted.
- **partially_fulfilled** — The Capacity Reservation Fleet has partially fulfilled its total target capacity. There is insufficient Amazon EC2 capacity to fulfill the total target capacity. The Fleet is attempting to asynchronously fulfill its total target capacity.
- **expiring** — The Capacity Reservation Fleet has reached its end date and it is in the process of expiring. One or more of its Capacity Reservations might still be active.
- **expired** — The Capacity Reservation Fleet has reached its end date. The Fleet and its Capacity Reservations are expired. The Fleet can't create new Capacity Reservations.
- **cancelling** — The Capacity Reservation Fleet is in the process of being cancelled. One or more of its Capacity Reservations might still be active.
- **cancelled** — The Capacity Reservation Fleet has been manually cancelled. The Fleet and its Capacity Reservations are cancelled and the Fleet can't create new Capacity Reservations.

- failed — The Capacity Reservation Fleet failed to reserve capacity for the specified instance types.

Create a Capacity Reservation Fleet

When you create a Capacity Reservation Fleet it automatically creates Capacity Reservations for the instance types specified in the Fleet request, up to the specified total target capacity. The number of instances for which the Capacity Reservation Fleet reserves capacity depends on the total target capacity and instance type weights that you specify in the request. For more information, see [Instance type weight \(p. 563\)](#) and [Total target capacity \(p. 562\)](#).

When you create the Fleet, you must specify the instance types to use and a priority for each of those instance types. For more information, see [Allocation strategy \(p. 563\)](#) and [Instance type priority \(p. 564\)](#).

Note

The **AWSServiceRoleForEC2CapacityReservationFleet** service-linked role is automatically created in your account the first time that you create a Capacity Reservation Fleet. For more information, see [Using Service-Linked Roles for Capacity Reservation Fleet \(p. 570\)](#).

Currently, Capacity Reservation Fleets support the `open` instance matching criteria only.

You can create a Capacity Reservation Fleet using the command line only.

To create a Capacity Reservation Fleet

Use the [create-capacity-reservation-fleet](#) AWS CLI command.

```
$ aws ec2 create-capacity-reservation-fleet \
--total-target-capacity capacity_units \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy dedicated/default \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--instance-type-specifications file://instanceTypeSpecification.json

Modify a Capacity Reservation Fleet

You can modify the total target capacity and date of a Capacity Reservation Fleet at any time. When you modify the total target capacity of a Capacity Reservation Fleet, the Fleet automatically creates new Capacity Reservations, or modifies or cancels existing Capacity Reservations in the Fleet to meet the new total target capacity. When you modify the end date for the Fleet, the end dates for all of the individual Capacity Reservations are updated accordingly.

After you modify a Fleet, its status transitions to `modifying`. You can't attempt additional modifications to a Fleet while it is in the `modifying` state.

You can't modify the tenancy, Availability Zone, instance types, instance platforms, priorities, or weights used by a Capacity Reservation Fleet. If you need to change any of these parameters, you might need to cancel the existing Fleet and create a new one with the required parameters.

You can modify a Capacity Reservation Fleet using the command line only.

To modify a Capacity Reservation Fleet

Use the [modify-capacity-reservation-fleet](#) AWS CLI command.

Note

You can't specify `--end-date` and `--remove-end-date` in the same command.

```
$ aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id cr_fleet_ids \
--total-target-capacity capacity_units \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--remove-end-date
```

Expected output

```
{  
    "Return": true  
}
```

Example: Modify total target capacity

```
$ aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--total-target-capacity 160
```

Example: Modify end date

```
$ aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--end-date 2021-07-04T23:59:59.000Z
```

Example: Remove end date

```
$ aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--remove-end-date
```

Example output

```
{  
    "Return": true  
}
```

Cancel a Capacity Reservation Fleet

When you no longer need a Capacity Reservation Fleet and the capacity it reserves, you can cancel it. When you cancel a Fleet, its status changes to `cancelled` and it can no longer create new Capacity Reservations. Additionally, all of the individual Capacity Reservations in the Fleet are cancelled and the instances that were previously running in the reserved capacity continue to run normally in shared capacity.

You can cancel a Capacity Reservation Fleet using the command line only.

To cancel a Capacity Reservation Fleet

Use the [cancel-capacity-reservation-fleet](#) AWS CLI command.

```
$ aws ec2 cancel-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

Expected output

  "SuccessfulFleetCancellations": [
    {
      "CurrentFleetState": "state",
      "PreviousFleetState": "state",
      "CapacityReservationFleetId": "cr_fleet_id_1"

          "Message": "message"
        }
      ]
    }
  ]
}
```

Example: Successful cancellation

```
$ aws ec2 cancel-capacity-reservation-fleets \
--capacity-reservation-fleet-ids crf-abcdef01234567890

Example Capacity Reservation Fleet configurations

Topics

- [Example 1: Reserve capacity based on vCPUs \(p. 570\)](#)

Example 1: Reserve capacity based on vCPUs

The following example creates a Capacity Reservation Fleet that uses two instance types: `m5.4xlarge` and `m5.12xlarge`.

It uses a weighting system based on the number of vCPUs provided by the specified instance types. The total target capacity is 480 vCPUs. The `m5.4xlarge` provides 16 vCPUs and gets a weight of 16, while the `m5.12xlarge` provides 48 vCPUs and gets a weight of 48. This weighting system configures the Capacity Reservation Fleet to reserve capacity for either 30 `m5.4xlarge` instances ($480/16=30$), or 10 `m5.12xlarge` instances ($480/48=10$).

The Fleet is configured to prioritize the `m5.12xlarge` capacity and gets priority of 1, while the `m5.4xlarge` gets a lower priority of 2. This means that the fleet will attempt to reserve the `m5.12xlarge` capacity first, and only attempt to reserve the `m5.4xlarge` capacity if Amazon EC2 has insufficient `m5.12xlarge` capacity.

The Fleet reserves the capacity for Windows instances and the reservation automatically expires on October 31, 2021 at 23:59:59 UTC.

```
$ aws ec2 create-capacity-reservation-fleet \
--total-target-capacity 48 \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy default \
--end-date 2021-10-31T23:59:59.000Z \

Using Service-Linked Roles for Capacity Reservation Fleet

On-Demand Capacity Reservation Fleet uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Capacity Reservation

Fleet. Service-linked roles are predefined by Capacity Reservation Fleet and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Capacity Reservation Fleet easier because you don't have to manually add the necessary permissions. Capacity Reservation Fleet defines the permissions of its service-linked roles, and unless defined otherwise, only Capacity Reservation Fleet can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Capacity Reservation Fleet resources because you can't inadvertently remove permission to access the resources.

Service-Linked Role Permissions for Capacity Reservation Fleet

Capacity Reservation Fleet uses the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to create, describe, modify, and cancel Capacity Reservations that were previously created by a Capacity Reservation Fleet, on your behalf.

The **AWSServiceRoleForEC2CapacityReservationFleet** service-linked role trusts the following entity to assume the role: `capacity-reservation-fleet.amazonaws.com`.

The role uses the **AWSEC2CapacityReservationFleetRolePolicy** policy, which includes the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeCapacityReservations",
                "ec2:DescribeInstances"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2>CreateCapacityReservation",
                "ec2:CancelCapacityReservation",
                "ec2:ModifyCapacityReservation"
            ],
            "Resource": [
                "arn:aws:ec2:::capacity-reservation/*"
            ],
            "Condition": {
                "StringLike": {
                    "ec2:CapacityReservationFleet": "arn:aws:ec2:::capacity-reservation-
fleet/crf-*"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2>CreateTags"
            ],
            "Resource": [
                "arn:aws:ec2:::capacity-reservation/*"
            ],
            "Condition": {
                "StringEquals": {

```

```
        "ec2:CreateAction": "CreateCapacityReservation"
    }
}
]
```

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

[Creating a Service-Linked Role for Capacity Reservation Fleet](#)

You don't need to manually create a service-linked role. When you create a Capacity Reservation Fleet using the `create-capacity-reservation-fleet` AWS CLI command or the `CreateCapacityReservationFleet` API, the service-linked role is automatically created for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Capacity Reservation Fleet, Capacity Reservation Fleet creates the service-linked role for you again.

[Editing a Service-Linked Role for Capacity Reservation Fleet](#)

Capacity Reservation Fleet does not allow you to edit the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

[Deleting a Service-Linked Role for Capacity Reservation Fleet](#)

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete the resources for your service-linked role before you can manually delete it.

Note

If the Capacity Reservation Fleet service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role

1. Use the `delete-capacity-reservation-fleet` AWS CLI command or the `DeleteCapacityReservationFleet` API to delete the Capacity Reservation Fleets in your account.
2. Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

[Supported Regions for Capacity Reservation Fleet Service-Linked Roles](#)

Capacity Reservation Fleet supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and Endpoints](#).

[CloudWatch metrics for On-Demand Capacity Reservations](#)

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

On-Demand Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see [Using Amazon CloudWatch Metrics](#). For more information about creating alarms, see [Creating Amazon CloudWatch Alarms](#).

Capacity Reservation usage metrics

The AWS/EC2CapacityReservations namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

Metric	Description
UsedInstanceCount	The number of instances that are currently in use. Unit: Count
AvailableInstanceCount	The number of instances that are available. Unit: Count
TotalInstanceCount	The total number of instances you have reserved. Unit: Count
InstanceUtilization	The percentage of reserved capacity instances that are currently in use. Unit: Percent

Capacity Reservation metric dimensions

You can use the following dimensions to refine the metrics listed in the previous table.

Dimension	Description
CapacityReservationId	This globally unique dimension filters the data you request for the identified capacity reservation only.

View CloudWatch metrics for Capacity Reservations

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

To view Capacity Reservation metrics using the CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see [Regions and Endpoints](#).

3. In the navigation pane, choose **Metrics**.
4. For **All metrics**, choose **EC2 Capacity Reservations**.
5. Choose the metric dimension **By Capacity Reservation**. Metrics will be grouped by **CapacityReservationId**.
6. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric.

To view Capacity Reservation metrics (AWS CLI)

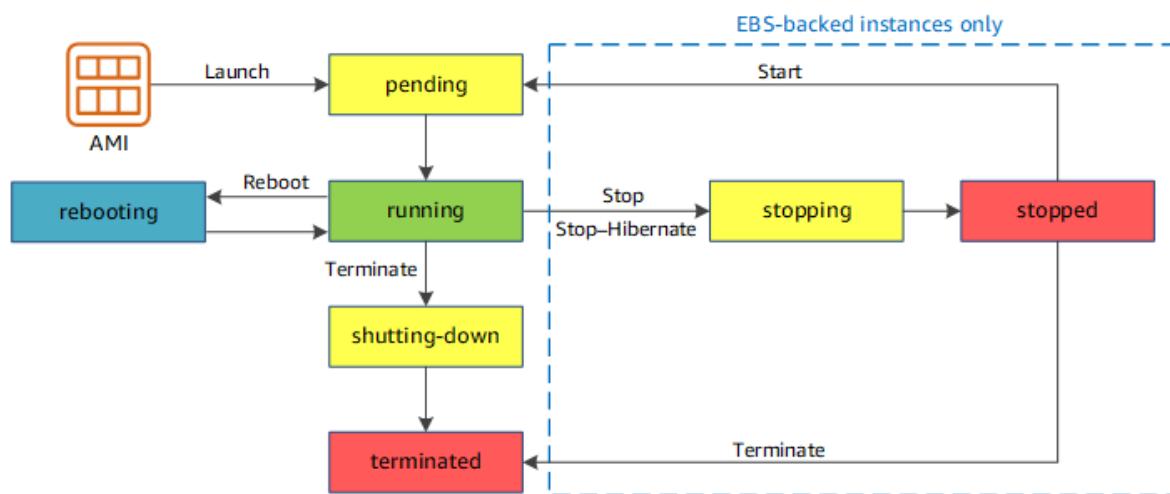

Use the following [list-metrics](#) command:

```
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

Instance lifecycle

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states. Notice that you can't stop and start an instance store-backed instance. For more information about instance store-backed instances, see [Storage for the root device \(p. 106\)](#).

The following table provides a brief description of each instance state and indicates whether it is billed or not.

Note

The table indicates billing for instance usage only. Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the *AWS Billing and Cost Management User Guide*.

Instance state	Description	Instance usage billing

Note

Rebooting an instance doesn't start a new instance billing period because the instance stays in the `running` state.

Instance launch

When you launch an instance, it enters the `pending` state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the `running` state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the `running` state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

For more information, see [Launch your instance \(p. 578\)](#) and [Connect to your Linux instance \(p. 611\)](#).

Instance stop and start (Amazon EBS-backed instances only)

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the stopping state, and then the stopped state. We don't charge usage or data transfer fees for your instance after you stop it, but we do charge for the storage for any Amazon EBS volumes. While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes on the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

Each time you transition an instance from stopped to running, we charge per second when the instance is running, with a minimum of one minute every time you start your instance.

For more information, see [Stop and start your instance \(p. 637\)](#).

Instance hibernate (Amazon EBS-backed instances only)

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the stopping state, and then the stopped state. We don't charge usage for a hibernated instance when it is in the stopped state, but we do charge while it is in the stopping state, unlike when you [stop an instance \(p. 575\)](#) without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see [Hibernate your On-Demand Linux instance \(p. 640\)](#).

Instance reboot

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see [Reboot your instance \(p. 657\)](#).

Instance retirement

An instance is scheduled to be retired when AWS detects the irreparable failure of the underlying hardware hosting the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information, see [Instance retirement \(p. 658\)](#).

Instance termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the `InstanceInitiatedShutdownBehavior` attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself (for example, by using the `shutdown` command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the `DeleteOnTermination` attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see [Terminate your instance \(p. 661\)](#).

Differences between reboot, stop, hibernate, and terminate

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate

Billing	The instance billing hour doesn't change.	You stop incurring charges for an instance as soon as its state changes to stopping. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You incur charges while the instance is in the stopping state, but stop incurring charges when the instance is in the stopped state. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You stop incurring charges for an instance as soon as its state changes to shutting-down.

Operating system shutdown commands always terminate an instance store-backed instance. You can control whether operating system shutdown commands stop or terminate an Amazon EBS-backed instance. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).

Launch your instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you sign up for AWS, you can get started with Amazon EC2 for free using the [AWS Free Tier](#). You can use the free tier to launch and use a `t2.micro` instance for free for 12 months (in Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the free tier). If you launch an instance

that is not within the free tier, you incur the standard Amazon EC2 usage fees for the instance. For more information, see [Amazon EC2 pricing](#).

You can launch an instance using the following methods.

Method	Documentation
[Amazon EC2 console] Use the launch instance wizard to specify the launch parameters.	Launch an instance using the Launch Instance Wizard (p. 580)
[Amazon EC2 console] Create a launch template and launch the instance from the launch template.	Launch an instance from a launch template (p. 594)
[Amazon EC2 console] Use an existing instance as the base.	Launch an instance using parameters from an existing instance (p. 608)
[Amazon EC2 console] Use an AMI that you purchased from the AWS Marketplace.	Launch an AWS Marketplace instance (p. 610)
[AWS CLI] Use an AMI that you select.	Using Amazon EC2 through the AWS CLI
[AWS Tools for Windows PowerShell] Use an AMI that you select.	Amazon EC2 from the AWS Tools for Windows PowerShell
[AWS CLI] Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchase models.	EC2 Fleet (p. 778)
[AWS CloudFormation] Use a AWS CloudFormation template to specify an instance.	AWS::EC2::Instance in the AWS CloudFormation User Guide
[AWS SDK] Use a language-specific AWS SDK to launch an instance.	AWS SDK for .NET AWS SDK for C++ AWS SDK for Go AWS SDK for Java AWS SDK for JavaScript AWS SDK for PHP V3 AWS SDK for Python AWS SDK for Ruby V3

Note

To launch an EC2 instance into an IPv6-only subnet, you must use [Instances built on the Nitro System \(p. 247\)](#).

Note

When launching an IPv6-only instance, it is possible that DHCPv6 may not immediately provide the instance with the IPv6 DNS name server. During this initial delay, the instance may not be able to resolve public domains.

For instances running on Amazon Linux 2, if you want to immediately update the /etc/resolv.conf file with the IPv6 DNS name server, run the following [cloud-init directive](#) at launch:

```
#cloud-config
bootcmd:
- /usr/bin/sed -i -E 's,^nameserver\s+[\.\[[:digit:]\]]+\$,nameserver fd00:ec2::253,' /
etc/resolv.conf
```

Another option is to change the configuration file and re-image your AMI so that the file has the IPv6 DNS name server address immediately on booting.

When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone - This option is the default.
- A Local Zone - To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see [Local Zones](#)
- A Wavelength Zone - To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see [Get started with AWS Wavelength](#) in the *AWS Wavelength Developer Guide*.
- An Outpost - To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see [Get Started with AWS Outposts](#) in the *AWS Outposts User Guide*.

After you launch your instance, you can connect to it and use it. To begin, the instance state is `pending`. When the instance state is `running`, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch. For more information about bare metal instances, see [Instances built on the Nitro System \(p. 247\)](#).

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance. For more information about connecting to your instance, see [Connect to your Linux instance \(p. 611\)](#).

When you are finished with an instance, be sure to terminate it. For more information, see [Terminate your instance \(p. 661\)](#).

Launch an instance using the Launch Instance Wizard

You can launch an instance using the launch instance wizard. The launch instance wizard specifies all the launch parameters required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. At the very least, you need to select an AMI and a key pair to launch an instance.

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2 \(p. 5\)](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

Steps to launch an instance:

- [Initiate instance launch \(p. 581\)](#)
- [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 581\)](#)
- [Step 2: Choose an Instance Type \(p. 582\)](#)
- [Step 3: Configure Instance Details \(p. 582\)](#)
- [Step 4: Add Storage \(p. 585\)](#)
- [Step 5: Add Tags \(p. 585\)](#)
- [Step 6: Configure Security Group \(p. 585\)](#)

- [Step 7: Review Instance Launch and Select Key Pair \(p. 586\)](#)
- [Launch an instance using the new launch instance wizard – beta \(p. 586\)](#)

Initiate instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current Region is displayed (for example, US East (Ohio)). Select a Region for the instance that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 1683\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

Step 1: Choose an Amazon Machine Image (AMI)

When you launch an instance, you must select a configuration, known as an Amazon Machine Image (AMI). An AMI contains the information required to create a new instance. For example, an AMI might contain the software required to act as a web server, such as Linux, Apache, and your website.

When you launch an instance, you can either select an AMI from the list, or you can select a Systems Manager parameter that points to an AMI ID. For more information, see [Using a Systems Manager parameter to find an AMI](#).

On the **Choose an Amazon Machine Image (AMI)** page, use one of two options to choose an AMI. Either [search the list of AMIs \(p. 581\)](#), or [search by Systems Manager parameter \(p. 582\)](#).

By searching the list of AMIs

1. Select the type of AMI to use in the left pane:

Quick Start

A selection of popular AMIs to help you get started quickly. To select an AMI that is eligible for the free tier, choose **Free tier only** in the left pane. These AMIs are marked **Free tier eligible**.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you. To view AMIs that are shared with you, choose **Shared with me** in the left pane.

AWS Marketplace

An online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance \(p. 610\)](#).

Community AMIs

The AMIs that AWS community members have made available for others to use. To filter the list of AMIs by operating system, choose the appropriate check box under **Operating system**. You can also filter by architecture and root device type.

2. Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need, either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device \(p. 106\)](#).
3. Check the **Virtualization type** listed for each AMI. Notice which AMIs are the type that you need, either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information, see [Linux AMI virtualization types \(p. 108\)](#).
4. Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need, either **legacy-bios** or **uefi**. For more information, see [Boot modes \(p. 110\)](#).

5. Choose an AMI that meets your needs, and then choose **Select**.

By Systems Manager parameter

1. Choose **Search by Systems Manager parameter** (at top right).
2. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
3. Choose **Search**. The AMIs that match the AMI ID appear in the list.
4. Select the AMI from the list, and choose **Select**.

Step 2: Choose an Instance Type

On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information, see [Instance types \(p. 240\)](#).

To remain eligible for the free tier, choose the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). For more information, see [Burstable performance instances \(p. 266\)](#).

By default, the wizard displays current generation instance types, and selects the first available instance type based on the AMI that you selected. To view previous generation instance types, choose **All generations** from the filter list.

Note

To set up an instance quickly for testing purposes, choose **Review and Launch** to accept the default configuration settings, and launch your instance. Otherwise, to configure your instance further, choose **Next: Configure Instance Details**.

Step 3: Configure Instance Details

On the **Configure Instance Details** page, change the following settings as necessary (expand **Advanced Details** to see all the settings), and then choose **Next: Add Storage**:

- **Number of instances:** Enter the number of instances to launch.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see [Health Checks for Auto Scaling Instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. This adds and removes options from this page. Set your maximum price, and optionally update the request type, interruption behavior, and request validity. For more information, see [Create a Spot Instance request \(p. 452\)](#).
- **Network:** Select the VPC, or to create a new VPC, choose **Create new VPC** to go the Amazon VPC console. When you have finished, return to the wizard and choose **Refresh** to load your VPC in the list.

- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone or Outpost.

To launch the instance in an Availability Zone, select the subnet into which to launch your instance. You can select **No preference** to let AWS choose a default subnet in any Availability Zone. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose **Refresh** to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with an Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses \(p. 1038\)](#).
- **Auto-assign IPv6 IP:** Specify whether your instance receives an IPv6 address from the range of the subnet. Select **Enable** or **Disable** to override the subnet's default setting. This option is only available if you've associated an IPv6 CIDR block with your VPC and subnet. For more information, see [Your VPC and Subnets in the Amazon VPC User Guide](#).
- **Hostname type:** Select if you want the guest OS hostname of the EC2 instance to be the Resource name or IP name. For more information about hostname type and these options, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **DNS Hostname:** Determines if the DNS queries to the IP name and/or the Resource name will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information about these options, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **Domain join directory:** Select the AWS Directory Service directory (domain) to which your Linux instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see [Seamlessly Join a Linux EC2 Instance to Your AWS Managed Microsoft AD Directory](#).
- **Placement group:** A placement group determines the placement strategy of your instances. Select an existing placement group, or create a new one. This option is only available if you've selected an instance type that supports placement groups. For more information, see [Placement groups \(p. 1190\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into shared capacity, any open Capacity Reservation, a specific Capacity Reservation, or a Capacity Reservation group. For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).
- **IAM role:** Select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1297\)](#).
- **CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options \(p. 691\)](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).
- **Stop - Hibernate behavior:** To enable hibernation, select this check box. This option is only available if your instance meets the hibernation prerequisites. For more information, see [Hibernate your On-Demand Linux instance \(p. 640\)](#).
- **Enable termination protection:** To prevent accidental termination, select this check box. For more information, see [Enable termination protection \(p. 663\)](#).
- **Monitoring:** Select this check box to enable detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 975\)](#).
- **EBS-optimized instance:** An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).

- **Tenancy:** If you are launching your instance into a VPC, you can choose to run your instance on isolated, dedicated hardware (**Dedicated**) or on a Dedicated Host (**Dedicated host**). Additional charges may apply. For more information, see [Dedicated Instances \(p. 531\)](#) and [Dedicated Hosts \(p. 498\)](#).
- **T2/T3 Unlimited:** Select this check box to enable applications to burst beyond the baseline for as long as needed. Additional charges may apply. For more information, see [Burstable performance instances \(p. 266\)](#).
- **File systems:** To create a new file system to mount to your instance, choose **Create new file system**, enter a name for the new file system, and then choose **Create**. The file system is created using Amazon EFS Quick Create, which applies the service recommended settings. The security groups required to enable access to the file system are automatically created and attached to the instance and the mount targets of the file system. You can also choose to manually create and attach the required security groups. For more information, see [Create an EFS file system using Amazon EFS Quick Create \(p. 1640\)](#).

To mount one or more existing Amazon EFS file systems to your instance, choose **Add file system** and then choose the file systems to mount and the mount points to use. For more information, see [Create an EFS file system and mount it to your instance \(p. 1641\)](#).

- **Network interfaces:** If you selected a specific subnet, you can specify up to two network interfaces for your instance:
 - For **Network Interface**, select **New network interface** to let AWS create a new interface, or select an existing, available network interface.
 - For **Primary IP**, enter a private IPv4 address from the range of your subnet, or leave **Auto-assign** to let AWS choose a private IPv4 address for you.
 - For **Secondary IP addresses**, choose **Add IP** to assign more than one private IPv4 address to the selected network interface.
 - (IPv6-only) For **IPv6 IPs**, choose **Add IP**, and enter an IPv6 address from the range of the subnet, or leave **Auto-assign** to let AWS choose one for you.
 - **Network Card Index:** The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
 - Choose **Add Device** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces \(p. 1091\)](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch \(p. 1042\)](#).

- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific kernel.
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.
- **Enclave:** Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.
- **Metadata accessible:** You can enable or disable access to the instance metadata. For more information, see [Use IMDSv2 \(p. 727\)](#).
- **Metadata transport:** You can enable or disable the access method to the instance metadata service that's available for this EC2 instance based on the IP address type (IPv4, IPv6, or IPv4 and IPv6) of the instance. For more information, see [Retrieve instance metadata \(p. 734\)](#).
- **Metadata version:** If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 731\)](#).
- **Metadata token response hop limit:** If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2 \(p. 727\)](#).

- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the **As file** option and browse for the file to attach.

Step 4: Add Storage

The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. Configure each volume as follows, and then choose **Next: Add Tags**.

- **Type:** Select instance store or Amazon EBS volumes to associate with your instance. The types of volume available in the list depend on the instance type you've chosen. For more information, see [Amazon EC2 instance store \(p. 1620\)](#) and [Amazon EBS volumes \(p. 1349\)](#).
- **Device:** Select from the list of available device names for the volume.
- **Snapshot:** Enter the name or ID of the snapshot from which to restore a volume. You can also search for available shared and public snapshots by typing text into the **Snapshot** field. Snapshot descriptions are case-sensitive.
- **Size:** For EBS volumes, you can specify a storage size. Even if you have selected an AMI and instance that are eligible for the free tier, to stay within the free tier, you must stay under 30 GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1368\)](#).
- **Volume Type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types \(p. 1352\)](#).
- **IOPS:** If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on Termination:** For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).
- **Encrypted:** If the instance type supports EBS encryption, you can specify the encryption state of the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or disable encryption. For more information, see [Amazon EBS encryption \(p. 1542\)](#).

Step 5: Add Tags

On the **Add Tags** page, specify [tags \(p. 1692\)](#) by providing key and value combinations. You can tag the instance, the volumes, or both. For Spot Instances, you can tag the Spot Instance request only. Choose **Add another tag** to add more than one tag to your resources. Choose **Next: Configure Security Group** when you are done.

Step 6: Configure Security Group

On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).) Select or create a security group as follows, and then choose **Review and Launch**.

- To select an existing security group, choose **Select an existing security group**, and select your security group. You can't edit the rules of an existing security group, but you can copy them to a new group by choosing **Copy to new**. Then you can add rules as described in the next step.
- To create a new security group, choose **Create a new security group**. The wizard automatically defines the launch-wizard-x security group and creates an inbound rule to allow you to connect to your instance over SSH (port 22).
- You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add Rule**, select the protocol to open to network traffic, and then specify the source. Choose **My IP** from the **Source** list to let the wizard add your computer's public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable for this short exercise, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

Step 7: Review Instance Launch and Select Key Pair

On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch**.

In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair you created when getting set up. For more information, see [Amazon EC2 key pairs and Linux instances \(p. 1310\)](#).

Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

(Optional) You can create a status check alarm for the instance (additional fees may apply). (If you're not sure, you can always add one later.) On the confirmation screen, choose **Create status check alarms** and follow the directions. For more information, see [Create and edit status check alarms \(p. 949\)](#).

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 1709\)](#).

Launch an instance using the new launch instance wizard – beta

This is prerelease documentation for the new launch instance wizard, which is in beta release. The documentation and the feature are both subject to change. For beta terms and conditions, see the [Betas and Previews section in the AWS Service Terms](#).

You can launch an instance using the launch instance wizard. The launch instance wizard specifies the launch parameters that are required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. If you accept the default values, then it's possible to launch an instance by selecting only a key pair.

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2 \(p. 5\)](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

About the new launch instance wizard

Welcome to the new and improved launch experience—a quicker and easier way to launch an instance.

Current improvements

- **Single page layout with summary side panel**

Quickly get up and running with our new one-page design. See all of your settings in one location. No need to navigate back and forth between steps to ensure your configuration is correct. Use the **Summary** panel for an overview and to easily navigate the page.

- **Improved AMI selector**

New users – Use the **Quick Start** AMI selector to select an operating system so that you can quickly launch an instance.

Experienced users – The AMI selector displays your recently used AMIs and the AMIs that you own, making it easier to select the AMIs that you care about. You can still browse the full catalog to find new AMIs.

Work in progress

We're working continuously to improve the experience. Here's what we're currently working on:

- **Missing features**
 - Missing features to be added in the future: Domain join, CPU options, EFS file system integration, and AMI selection by using an Amazon EC2 Systems Manager parameter.
- **Defaults and dependency assistance**
 - **Default values** will be provided for all fields.
 - **Additional logic** will be added to help you set up your instance configuration correctly (for example, we'll disable parameters that are not available with your current settings).
- **Further simplified designs**
 - **Simplified views and summaries** and a **more responsive design** will be added to make the one-page experience more scalable.
 - **Simplified networking** features will be added to help you to configure your firewall rules quickly and easily (for example, we'll select common preset rules).

There will be many more improvements to the launch experience in the months ahead.

We're in the process of rolling out the new launch instance wizard to several AWS Regions. If it's not available in your currently selected Region, you can select a different Region to check if it's available there.

Please send feedback

We'd appreciate your feedback on this early release. We'll use your feedback to continue improving the experience over the next few months. You can send us feedback directly from the EC2 console, or use the **Provide feedback** link at the bottom of this page.

Quickly launch an instance

To set up an instance quickly for testing purposes, follow these steps. You'll select the operating system and your key pair, and accept the default values. For information about all of the parameters in the launch instance wizard, see [Launch an instance using defined parameters \(p. 588\)](#).

To quickly launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 1683\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. To use the new launch instance wizard, choose **Try it now!** at the top right of the screen. If **Try it now!** is not visible, the new launch instance wizard is not yet available in the currently selected Region.
5. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
6. Under **Application and OS Images (Amazon machine Image)**, choose **Quick Start**, and then choose the operating system (OS) for your instance.
7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
8. In the **Summary** panel, choose **Launch instance**.

Launch an instance using defined parameters

Except for the key pair, the launch instance wizard provides default values for all of the parameters. You can accept any or all of the defaults, or configure an instance by specifying your own values for each parameter. The parameters are grouped in the launch instance wizard. The following instructions take you through each parameter group.

Parameters for instance configuration

- [Initiate instance launch \(p. 588\)](#)
- [Name and tags \(p. 589\)](#)
- [Application and OS Images \(Amazon Machine Image\) \(p. 589\)](#)
- [Instance type \(p. 590\)](#)
- [Key pair \(login\) \(p. 590\)](#)
- [Network settings \(p. 590\)](#)
- [Configure storage \(p. 592\)](#)
- [Advanced details \(p. 592\)](#)
- [Summary \(p. 594\)](#)

Initiate instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 1683\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. To use the new launch instance wizard, choose **Try it now!** at the top right of the screen. If **Try it now!** is not visible, the new launch instance wizard is not yet available in the currently selected Region.

Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, the volumes, and elastic graphics. For Spot Instances, you can tag the Spot Instance request only. For information about tags, see [Tag your Amazon EC2 resources \(p. 1692\)](#).

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch instance wizard without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance \(p. 610\)](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.

- Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device \(p. 106\)](#).
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information, see [Linux AMI virtualization types \(p. 108\)](#).
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios** or **uefi**. For more information, see [Boot modes \(p. 110\)](#).
- Choose an AMI that meets your needs, and then choose **Select**.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#).

- For **Instance type**, select the instance type for the instance.

If your AWS account is less than 12 months old, you can use EC2 under the Free Tier by selecting the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). For more information about t2.micro and t3.micro, see [Burstable performance instances \(p. 266\)](#).

- **Compare instance types:** You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.

Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Linux instances \(p. 1310\)](#).

Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Network settings

Configure the network settings, as necessary.

- **Networking platform:** If applicable, whether to launch the instance into a VPC or EC2-Classic. If you choose **Virtual Private Cloud (VPC)**, specify the subnet in the **Network interfaces** section. If you choose **EC2-Classic**, ensure that the specified instance type is supported in EC2-Classic and then specify the Availability Zone for the instance. Note that we are retiring EC2-Classic on August 15, 2022.
- **VPC:** Select an existing VPC in which to create the security group.
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address, and instances in a nondefault subnet do

not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses \(p. 1038\)](#).

- **Firewall (security groups):** Use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).

If you add a network interface, you must specify the same security group in the network interface.

Select or create a security group as follows:

- To select an existing security group, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group, choose **Create security group**. The wizard automatically defines the **launch-wizard-x** security group and creates an inbound rule to allow you to connect to your instance over SSH (port 22).

You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source type**, select the source type. To let the wizard add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration** – Available only if you choose a subnet.

Network interface

- **Device index:** The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
- **Network interface:** Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description:** (Optional) A description for the new network interface.
- **Subnet:** The subnet in which to create the new network interface. For the primary network interface (eth0), this is the subnet in which the instance is launched. If you've entered an existing network interface for eth0, the instance is launched in the subnet in which the network interface is located.
- **Security groups:** One or more security groups in your VPC with which to associate the network interface.
- **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP:** One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **(IPv6-only) IPv6 IPs:** An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **IPv4 Prefixes:** The IPv4 prefixes for the network interface.
- **IPv6 Prefixes:** The IPv6 prefixes for the network interface.

- **Delete on termination:** Whether the network interface is deleted when the instance is deleted.
- **Elastic Fabric Adapter:** Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).

Choose **Add network interface** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces \(p. 1091\)](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch \(p. 1042\)](#).

Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

By using the **Advanced** view, you can configure each volume as follows:

- **Volume type:** Select Amazon EBS or instance store volumes to associate with your instance. The volume types available in the list depend on the instance type that you've chosen. For more information, see [Amazon EC2 instance store \(p. 1620\)](#) and [Amazon EBS volumes \(p. 1349\)](#).
- **Device name:** Select from the list of available device names for the volume.
- **Snapshot:** Select the snapshot from which to restore the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB):** For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1368\)](#).
- **Volume type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types \(p. 1352\)](#).
- **IOPS:** If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on termination:** For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).
- **Encrypted:** If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption \(p. 1542\)](#).
- **Key:** If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize** to change the default Spot Instance settings.

You can set your maximum price, and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see [Spot Instances \(p. 439\)](#).

- **IAM instance profile:** Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1297\)](#).
- **Hostname type:** Select if you want the guest OS hostname of the EC2 instance to be the Resource name (RBN) or IP name (IPBN). For more information about hostname type and these options, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **DNS Hostname:** Determines if the DNS queries to the IP name and/or the Resource name will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information about these options, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).
- **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is available only if your instance meets the hibernation prerequisites. For more information, see [Hibernate your On-Demand Linux instance \(p. 640\)](#).
- **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection \(p. 663\)](#).
- **Detailed CloudWatch monitoring:** Choose **Enable** to enable detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 975\)](#).
- **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for T instances. Additional charges may apply. For more information, see [Burstable performance instances \(p. 266\)](#).
- **Placement group name:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types support launching an instance in a placement group. For more information, see [Placement groups \(p. 1190\)](#).
- **EBS-optimized instance:** An instance that's optimized for Amazon EBS uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, choose **Enable** to enable it. Additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances \(p. 531\)](#) and [Dedicated Hosts \(p. 498\)](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the [AWS Nitro Enclaves User Guide](#).
- **Metadata accessible:** You can enable or disable access to the instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 731\)](#).
- **Metadata version:** If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 731\)](#).

- **Metadata response hop limit:** If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances \(p. 731\)](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Linux instance at launch \(p. 720\)](#).

Summary

Use the **Summary** panel to specify the number of instances to launch, to review your instance configuration, and to launch your instances.

- **Number of instances:** Enter the number of instances to launch. All of the instances will launch with the same configuration.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- Review the details of your instance, and make any necessary changes. You can navigate directly to a section by choosing its link in the **Summary** panel.
- When you're ready to launch your instance, choose **Launch instance**.

If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see [Troubleshoot instance launch issues \(p. 1709\)](#).

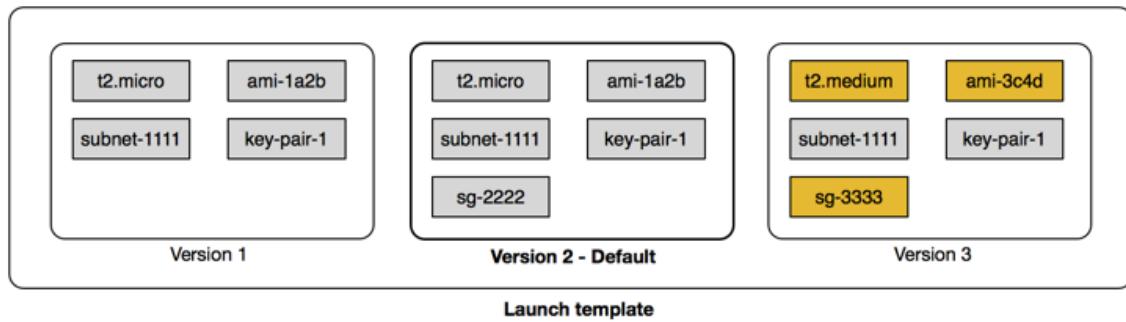

(Optional) You can create a billing alert for the instance. (If you're not sure, you can always add one later.) On the confirmation screen, Under **Next Steps**, choose **Create billing alerts** and follow the directions.

Launch an instance from a launch template

You can create a *launch template* that contains the configuration information to launch an instance. You can use launch templates to store launch parameters so that you do not have to specify them every time you launch an instance. For example, a launch template can contain the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template to use.

For each launch template, you can create one or more numbered *launch template versions*. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you do not specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it's the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.

Launch template restrictions

The following rules apply to launch templates and launch template versions:

- You are limited to creating 5,000 launch templates per Region and 10,000 versions per launch template.
- Launch template parameters are optional. However, you must ensure that your request to launch an instance includes all required parameters. For example, if your launch template does not include an AMI ID, you must specify both the launch template and an AMI ID when you launch an instance.
- Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values for parameters, or if you do not use supported parameter combinations, no instances can launch using this launch template. Ensure that you specify the correct values for the parameters and that you use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.
- You can tag a launch template, but you cannot tag a launch template version.
- Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
- Launch template versions are numbered in the order in which they are created. When you create a launch template version, you cannot specify the version number yourself.

Use launch templates to control launch parameters

A launch template can contain all or some of the parameters to launch an instance. When you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

Note

You cannot remove launch template parameters during launch (for example, you cannot specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, IAM users must have permissions to use the `ec2:RunInstances` action. IAM users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the `ec2:RunInstances` action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see [Launch templates \(p. 1273\)](#).

Control the use of launch templates

By default, IAM users do not have permissions to work with launch templates. You can create an IAM user policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user's ability to use specific resources for those actions. For more information, see the following example policies: [Example: Work with launch templates \(p. 1284\)](#).

Take care when granting users permissions to use the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You cannot use resource-level permissions to control which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

Create a launch template

Create a new launch template using parameters that you define, or use an existing launch template or an instance as the basis for a new launch template.

Tasks

- [Create a new launch template using parameters you define \(p. 596\)](#)
- [Create a launch template from an existing launch template \(p. 601\)](#)
- [Create a launch template from an instance \(p. 601\)](#)

Create a new launch template using parameters you define

Console

To create a new launch template using defined parameters using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. To tag the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair.
6. For **Amazon machine image (AMI)**, provide the following information:

- **AMI:** An AMI from which to launch the instance. To search through all available AMIs, choose **Search for AMI**. To select a commonly used AMI, choose **Quick Start**. Or, choose **AWS Marketplace** or **Community AMIs**. You can use an AMI that you own or [find a suitable AMI](#).
7. For **Instance type**, you can either select an instance type, or you can specify instance attributes and let Amazon EC2 identify the instance types with those attributes.

Note

Specifying instance attributes is supported only when using Auto Scaling groups, EC2 Fleet, and Spot Fleet to launch instances. For more information, see [Creating an Auto Scaling group using attribute-based instance type selection](#), [Attribute-based instance type selection for EC2 Fleet \(p. 801\)](#), and [Attribute-based instance type selection for Spot Fleet \(p. 842\)](#).

If you plan to use the launch template in the launch instance wizard or with the `RunInstances` API, you must select an instance type.

- **Instance type:** Ensure that the instance type is compatible with the AMI that you've specified. For more information, see [Instance types \(p. 240\)](#).
 - **Advanced:** To specify instance attributes and let Amazon EC2 identify the instance types with those attributes, choose **Advanced**, and then choose **Specify instance type attributes**.
 - **Number of vCPUs:** Enter the minimum and maximum number of vCPUs for your compute requirements. To indicate no limits, enter a minimum of 0, and leave the maximum blank.
 - **Amount of memory (MiB):** Enter the minimum and maximum amount of memory, in MiB, for your compute requirements. To indicate no limits, enter a minimum of 0, and leave the maximum blank.
 - Expand **Optional instance type attributes** and choose **Add attribute** to express your compute requirements in more detail. For information about each attribute, see [InstanceRequirementsRequest](#) in the *Amazon EC2 API Reference*.
 - **Resulting instance types:** You can preview the instance types that match the specified attributes. To exclude instance types, choose **Add attribute**, and from the **Attribute** list, choose **Excluded instance types**. From the **Attribute value** list, select the instance types to exclude.
8. For **Key pair (login)**, provide the following information:
- **Key pair name:** The key pair for the instance. For more information, see [Amazon EC2 key pairs and Linux instances \(p. 1310\)](#).
9. For **Network settings**, provide the following information:
- **Networking platform:** If applicable, whether to launch the instance into a VPC or EC2-Classic. If you choose **Virtual Private Cloud (VPC)**, specify the subnet in the **Network interfaces** section. If you choose **EC2-Classic**, ensure that the specified instance type is supported in EC2-Classic and specify the Availability Zone for the instance. Note that we are retiring EC2-Classic on August 15, 2022.
 - **Security groups:** One or more security groups to associate with the instance. If you add a network interface to the launch template, omit this setting and specify the security groups as part of the network interface specification. You cannot launch an instance from a launch template that specifies security groups and a network interface. For more information, see [Amazon EC2 security groups for Linux instances \(p. 1325\)](#).
10. For **Storage (volumes)**, specify volumes to attach to the instance besides the volumes specified by the AMI (**Volume 1 (AMI Root)**). To add a new volume, choose **Add new volume**.
- **Volume type:** The instance store or Amazon EBS volumes with which to associate your instance. The type of volume depends on the instance type that you've chosen. For more information, see [Amazon EC2 instance store \(p. 1620\)](#) and [Amazon EBS volumes \(p. 1349\)](#).
 - **Device name:** A device name for the volume.

- **Snapshot:** The ID of the snapshot from which to create the volume.
 - **Size (GiB):** For Amazon EBS volumes, the storage size.
 - **Volume type:** For Amazon EBS volumes, the volume type. For more information, see [Amazon EBS volume types \(p. 1352\)](#).
 - **IOPS:** For the Provisioned IOPS SSD volume type, the number of I/O operations per second (IOPS) that the volume can support.
 - **Delete on termination:** For Amazon EBS volumes, whether to delete the volume when the instance is terminated. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).
 - **Encrypted:** If the instance type supports EBS encryption, you can enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption \(p. 1542\)](#).
 - **Key:** The customer managed key to use for EBS encryption. You can specify the ARN of any customer managed key that you created using the customer managed key. If you specify a customer managed key, you must also use **Encrypted** to enable encryption.
11. For **Resource tags**, specify [tags \(p. 1692\)](#) by providing key and value combinations. You can tag the instance, the volumes, elastic graphics, Spot Instance requests, and network interfaces.
12. For **Network interfaces**, you can specify up to two [network interfaces \(p. 1091\)](#) for the instance.
- **Device index:** The device number for the network interface, for example, eth0 for the primary network interface. If you leave the field blank, AWS creates the primary network interface.
 - **Network interface:** The ID of the network interface, or leave blank to let AWS create a new network interface.
 - **Description:** (Optional) A description for the new network interface.
 - **Subnet:** The subnet in which to create a new network interface. For the primary network interface (eth0), this is the subnet in which the instance is launched. If you've entered an existing network interface for eth0, the instance is launched in the subnet in which the network interface is located.
 - **Security groups:** One or more security groups in your VPC with which to associate the network interface.
 - **Auto-assign public IP:** Whether to automatically assign a public IP address to the network interface with the device index of eth0. This setting can only be enabled for a single, new network interface.
 - **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let AWS choose a private IPv4 address for you.
 - **Secondary IP:** A secondary private IPv4 address from the range of your subnet. Leave blank to let AWS choose one for you.
 - **(IPv6-only) IPv6 IPs:** An IPv6 address from the range of the subnet.
 - **IPv4 Prefixes:** The IPv4 prefixes for the network interface.
 - **IPv6 Prefixes:** The IPv6 prefixes for the network interface.
 - **Delete on termination:** Whether the network interface is deleted when the instance is deleted.
 - **Elastic Fabric Adapter:** Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).
 - **Network card index:** The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
13. For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** The purchasing model. Choose [Request Spot Instances](#) to request Spot Instances at the Spot price, capped at the On-Demand price, and choose [Customize](#) to change the default Spot Instance settings. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see [Spot Instances \(p. 439\)](#).
- **IAM instance profile:** An AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1297\)](#).
- **Hostname type:** Determines if you want the guest OS hostname of the EC2 instance to be the Resource name (RBN) or IP name (IPBN). For more information, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **DNS Hostname:** Determines if the DNS queries to the IP name and/or the Resource name will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types \(p. 1053\)](#).
- **Shutdown behavior:** Whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).
- **Stop - Hibernate behavior:** Whether the instance is enabled for hibernation. This field is only valid for instances that meet the hibernation prerequisites. For more information, see [Hibernate your On-Demand Linux instance \(p. 640\)](#).
- **Termination protection:** Whether to prevent accidental termination. For more information, see [Enable termination protection \(p. 663\)](#).
- **Detailed CloudWatch monitoring:** Whether to enable detailed monitoring of the instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 975\)](#).
- **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference in the Amazon Elastic Inference Developer Guide](#).
- **Credit specification:** Whether to enable applications to burst beyond the baseline for as long as needed. This field is only valid for T instances. Additional charges may apply. For more information, see [Burstable performance instances \(p. 266\)](#).
- **Placement group name:** Specify a placement group in which to launch the instance. Not all instance types can be launched in a placement group. For more information, see [Placement groups \(p. 1190\)](#).
- **EBS-optimized instance:** Provides additional, dedicated capacity for Amazon EBS I/O. Not all instance types support this feature, and additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1562\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (Open), a specific Capacity Reservation (Target by ID), or a Capacity Reservation group (Target by group). To specify that a Capacity Reservation should not be used, choose None. For more information, see [Launch instances into an existing Capacity Reservation \(p. 543\)](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances \(p. 531\)](#) and [Dedicated Hosts \(p. 498\)](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) A RAM disk for the instance. If you have specified a kernel, you may need to specify a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) A kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. For more information, see [What is AWS Nitro Enclaves?](#) in the [AWS Nitro Enclaves User Guide](#).

- **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a License Configuration](#) in the [AWS License Manager User Guide](#).
- **Metadata accessible:** Whether to enable or disable access to the instance metadata. For more information, see [Use IMDSv2 \(p. 727\)](#).
- **Metadata transport:** Whether to enable or disable the access method to the instance metadata service that's available for this EC2 instance based on the IP address type (IPv4, IPv6, or IPv4 and IPv6) of the instance. For more information, see [Retrieve instance metadata \(p. 734\)](#).
- **Metadata version:** If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 731\)](#).
- **Metadata response hop limit:** If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2 \(p. 727\)](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Linux instance at launch \(p. 720\)](#).

14. Choose **Create launch template**.

AWS CLI

To create a launch template using the AWS CLI

- Use the [create-launch-template](#) command. The following example creates a launch template that specifies the following:
 - A tag for the launch template (`purpose=production`)
 - The instance type (`r4.4xlarge`) and AMI (`ami-8c1be5f6`) to launch
 - The number of cores (4) and threads per core (2) for a total of 8 vCPUs (4 cores x 2 threads)
 - The subnet in which to launch the instance (`subnet-7b16de0c`)

The template assigns a public IP address and an IPv6 address to the instance and creates a tag for the instance(`Name=webserver`).

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForWebServer \
    --version-description WebVersion1 \
    --tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
    --launch-template-data file://template-data.json
```

The following is an example `template-data.json` file.

```
{
    "NetworkInterfaces": [
        {
            "AssociatePublicIpAddress": true,
            "DeviceIndex": 0,
            "Ipv6AddressCount": 1,
            "SubnetId": "subnet-7b16de0c"
        }
    ],
    "ImageId": "ami-8c1be5f6",
    "InstanceType": "r4.4xlarge",
    "TagSpecifications": [
        {
            "ResourceType": "instance",

```

```
        "Tags": [{  
            "Key": "Name",  
            "Value": "webserver"  
        }]  
    },  
    "CpuOptions": {  
        "CoreCount": 4,  
        "ThreadsPerCore": 2  
    }  
}
```

The following is example output.

```
{  
    "LaunchTemplate": {  
        "LatestVersionNumber": 1,  
        "LaunchTemplateId": "lt-01238c059e3466abc",  
        "LaunchTemplateName": "TemplateForWebServer",  
        "DefaultVersionNumber": 1,  
        "CreatedBy": "arn:aws:iam::123456789012:root",  
        "CreateTime": "2017-11-27T09:13:24.000Z"  
    }  
}
```

Create a launch template from an existing launch template

To create a launch template from an existing launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. To tag the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair.
6. Expand **Source template**, and for **Launch template name** choose a launch template on which to base the new launch template.
7. For **Source template version**, choose the launch template version on which to base the new launch template.
8. Adjust any launch parameters as required, and then choose **Create launch template**.

Create a launch template from an instance

Console

To create a launch template from an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Actions, Create template from instance**.
4. Provide a name, description, and tags, and adjust the launch parameters as required.

Note

When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.

5. Choose **Create launch template**.

AWS CLI

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.

To get launch template data from an instance using the AWS CLI

- Use the [get-launch-template-data](#) command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level `LaunchTemplateData` object, which cannot be specified in your launch template data. Use the `--query` option to exclude this object.

```
aws ec2 get-launch-template-data \
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData"
```

The following is example output.

```
{
    "Monitoring": {},
    "ImageId": "ami-8c1be5f6",
    "BlockDeviceMappings": [
        {
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "DeleteOnTermination": true
            }
        }
    ],
    "EbsOptimized": false,
    "Placement": {
        "Tenancy": "default",
        "GroupName": "",
        "AvailabilityZone": "us-east-1a"
    },
    "InstanceType": "t2.micro",
    "NetworkInterfaces": [
        {
            "Description": "",
            "NetworkInterfaceId": "eni-35306abc",
            "PrivateIpAddresses": [
                {
                    "Primary": true,
                    "PrivateIpAddress": "10.0.0.72"
                }
            ],
            "SubnetId": "subnet-7b16de0c",
            "Groups": [
                "sg-7c227019"
            ],
            "Ipv6Addresses": [
                {
                    "Ipv6Address": "2001:db8:1234:1a00::123"
                }
            ],
            "PrivateIpAddress": "10.0.0.72"
        }
    ]
}
```

You can write the output directly to a file, for example:

```
aws ec2 get-launch-template-data \
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData" >> instance-data.json
```

To create a launch template using launch template data

Use the [create-launch-template](#) command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see [Create a new launch template using parameters you define \(p. 596\)](#).

Modify a launch template (manage launch template versions)

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.

You can create different versions of a launch template, set the default version, describe a launch template version, and delete versions that you no longer require.

Tasks

- [Create a launch template version \(p. 603\)](#)
- [Set the default launch template version \(p. 604\)](#)
- [Describe a launch template version \(p. 604\)](#)
- [Delete a launch template version \(p. 605\)](#)

Create a launch template version

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For more information about the launch parameters, see [Create a launch template \(p. 596\)](#).

Console

To create a launch template version using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select a launch template, and then choose **Actions, Modify template (Create new version)**.
4. For **Template version description**, enter a description for this version of the launch template.
5. (Optional) Expand **Source template** and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required, and choose **Create launch template**.

AWS CLI

To create a launch template version using the AWS CLI

- Use the [create-launch-template-version](#) command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `--launch-template-data`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```
aws ec2 create-launch-template-version \
--launch-template-id lt-0abcd290751193123 \
--version-description WebVersion2 \
--source-version 1 \
--launch-template-data "ImageId=ami-c998b6b2"
```

Set the default launch template version

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

Console

To set the default launch template version using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Set default version**.
4. For **Template version**, select the version number to set as the default version and choose **Set as default version**.

AWS CLI

To set the default launch template version using the AWS CLI

- Use the [modify-launch-template](#) command and specify the version that you want to set as the default.

```
aws ec2 modify-launch-template \
--launch-template-id lt-0abcd290751193123 \
--default-version 2
```

Describe a launch template version

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI, you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

Console

To describe a launch template version using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
 - To view a version of a launch template: Select the launch template. On the **Versions** tab, from **Version**, select a version to view its details.
 - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose **Latest version**, and then choose a version number.

- To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose **Default version**, and then choose a version number.

AWS CLI

To describe a launch template version using the AWS CLI

- Use the [describe-launch-template-versions](#) command and specify the version numbers. In the following example, versions 1 and 3 are specified.

```
aws ec2 describe-launch-template-versions \
--launch-template-id lt-0abcd290751193123 \
--versions 1 3
```

To describe all the latest and default launch template versions in your account using the AWS CLI

- Use the [describe-launch-template-versions](#) command and specify `$Latest`, `$Default`, or both. You must omit the launch template ID and name in the call. You cannot specify version numbers.

```
aws ec2 describe-launch-template-versions \
--versions "$Latest,$Default"
```

Delete a launch template version

If you no longer require a launch template version, you can delete it. You cannot replace the version number after you delete it. You cannot delete the default version of the launch template; you must first assign a different version as the default.

Console

To delete a launch template version using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template version**.
4. Select the version to delete and choose **Delete**.

AWS CLI

To delete a launch template version using the AWS CLI

- Use the [delete-launch-template-versions](#) command and specify the version numbers to delete.

```
aws ec2 delete-launch-template-versions \
--launch-template-id lt-0abcd290751193123 \
--versions 1
```

Launch an instance from a launch template

You can use the parameters contained in a launch template to launch an instance. You have the option to override or add launch parameters before you launch the instance.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You cannot remove or edit these tags.

Console

To launch an instance from a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Launch instance from template**.
4. For **Source template version**, select the launch template version to use.
5. For **Number of instances**, specify the number of instances to launch.
6. (Optional) You can override or add launch template parameters by changing and adding parameters in the **Instance details** section.
7. Choose **Launch instance from template**.

AWS CLI

To launch an instance from a launch template using the AWS CLI

- Use the `run-instances` command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
aws ec2 run-instances \
  --launch-template LaunchTemplateId=lt-0abcd290751193123,Version=1
```

- To override a launch template parameter, specify the parameter in the `run-instances` command. The following example overrides the instance type that's specified in the launch template (if any).

```
aws ec2 run-instances \
  --launch-template LaunchTemplateId=lt-0abcd290751193123 \
  --instance-type t2.small
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag `Owner=TeamA` as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of `Owner`, the value is replaced with `TeamA`.

```
aws ec2 run-instances \
  --launch-template LaunchTemplateId=lt-0abcd290751193123 \
  --tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the

launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```
aws ec2 run-instances \
--launch-template LaunchTemplateId=lt-0abcd290751193123 \
--block-device-mappings "DeviceName=/dev/xvdb,Ebs={VolumeSize=20,VolumeType=gp2}"
```

If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see [Troubleshoot instance launch issues \(p. 1709\)](#).

Use launch templates with Amazon EC2 Auto Scaling

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch parameters defined in the associated launch template. For more information, see [Creating an Auto Scaling Group Using a Launch Template](#) in the *Amazon EC2 Auto Scaling User Guide*.

Before you can create an Auto Scaling group using a launch template, you must create a launch template that includes the parameters required to launch an instance in an Auto Scaling group, such as the ID of the AMI. The console provides guidance to help you create a template that you can use with Auto Scaling.

To create a launch template to use with Auto Scaling using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. Under **Auto Scaling guidance**, select the check box to have Amazon EC2 provide guidance to help create a template to use with Auto Scaling.
6. Modify the launch parameters as required. Because you selected Auto Scaling guidance, some fields are required and some fields are not available. For considerations to keep in mind when creating a launch template, and for information about how to configure the launch parameters for Auto Scaling, see [Creating a launch template for an Auto Scaling group](#) in the *Amazon EC2 Auto Scaling User Guide*.
7. Choose **Create launch template**.
8. (Optional) To create an Auto Scaling group using this launch template, in the **Next steps** page, choose **Create Auto Scaling group**.

To create or update an Amazon EC2 Auto Scaling group with a launch template using the AWS CLI

- Use the [create-auto-scaling-group](#) or the [update-auto-scaling-group](#) command and specify the `--launch-template` parameter.

Use launch templates with EC2 Fleet

You can create an EC2 Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create an EC2 Fleet \(p. 828\)](#).

To create an EC2 Fleet with a launch template using the AWS CLI

- Use the [create-fleet](#) command. Use the `--launch-template-configs` parameter to specify the launch template and any overrides for the launch template.

Use launch templates with Spot Fleet

You can create a Spot Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Spot Fleet request types \(p. 839\)](#).

To create a Spot Fleet request with a launch template using the AWS CLI

- Use the [request-spot-fleet](#) command. Use the `LaunchTemplateConfigs` parameter to specify the launch template and any overrides for the launch template.

Delete a launch template

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions.

Console

To delete a launch template (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template**.
4. Enter **Delete** to confirm deletion, and then choose **Delete**.

AWS CLI

To delete a launch template (AWS CLI)

- Use the [delete-launch-template](#) (AWS CLI) command and specify the launch template.

```
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

Launch an instance using parameters from an existing instance

The Amazon EC2 console provides a **Launch more like this** wizard option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch wizard with certain configuration details from the selected instance.

Note

The **Launch more like this** wizard option does not clone your selected instance; it only replicates some configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI.

Alternatively, create a [launch template \(p. 594\)](#) to store the launch parameters for your instances.

The following configuration details are copied from the selected instance into the launch wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address - regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see [Public IPv4 addresses \(p. 1038\)](#).
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)
- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- Number of network interfaces: The default is one network interface, which is the primary network interface (eth0).
- Storage: The default storage configuration is determined by the AMI and the instance type.

New console

To use your current instance as a template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to use, and then choose **Actions, Images and templates, Launch more like this**.
4. The launch wizard opens on the **Review Instance Launch** page. You can make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch** to select a key pair and launch your instance.

5. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 1709\)](#).

Old console

To use your current instance as a template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to use, and then choose **Actions, Launch More Like This**.

4. The launch wizard opens on the **Review Instance Launch** page. You can make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch** to select a key pair and launch your instance.

5. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 1709\)](#).

Launch an AWS Marketplace instance

You can subscribe to an AWS Marketplace product and launch an instance from the product's AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see [Paid AMIs \(p. 140\)](#). To cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see [Manage your AWS Marketplace subscriptions \(p. 143\)](#).

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Amazon EC2 dashboard, choose **Launch instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the **AWS Marketplace** category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Choose **Select** to choose your product.
4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose **Continue**.

Note

You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard. Additional taxes may also apply to the product.

5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. When you're done, choose **Next: Configure Instance Details**.
6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#). Choose **Next** until you reach the **Configure Security Group** page.

The wizard creates a new security group according to the vendor's specifications for the product. The security group may include rules that allow all IPv4 addresses (0 . 0 . 0 /0) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

When you are ready, choose **Review and Launch**.

7. On the **Review Instance Launch** page, check the details of the AMI from which you're about to launch the instance, as well as the other configuration details you set up in the wizard. When you're ready, choose **Launch** to select or create a key pair, and launch your instance.
8. Depending on the product you've subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View Instances** to go to the Instances page.

Note

You are charged the subscription price as long as your instance is running, even if it is idle. If your instance is stopped, you may still be charged for storage.

9. When your instance is in the `running` state, you can connect to it. To do this, select your instance in the list and choose **Connect**. Follow the instructions in the dialog. For more information about connecting to your instance, see [Connect to your Linux instance \(p. 611\)](#).

Important

Check the vendor's usage instructions carefully, as you may need to use a specific user name to log in to the instance. For more information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions \(p. 143\)](#).

10. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 1709\)](#).

Launch an AWS Marketplace AMI instance using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

Method	Documentation
AWS CLI	Use the run-instances command, or see the following topic for more information: Launching an Instance .
AWS Tools for Windows PowerShell	Use the New-EC2Instance command, or see the following topic for more information: Launch an Amazon EC2 Instance Using Windows PowerShell
Query API	Use the RunInstances request.

Connect to your Linux instance

Connect to the Linux instances that you launched and transfer files between your local computer and your instance.

To connect to a Windows instance, see [Connect to your Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

Connection options

The operating system of your local computer determines the options that you have to connect from your local computer to your Linux instance.

If your local computer operating system is Linux or macOS X

- [SSH client \(p. 614\)](#)
- [EC2 Instance Connect \(p. 617\)](#)
- [AWS Systems Manager Session Manager](#)

If your local computer operating system is Windows

- [PuTTY \(p. 627\)](#)
- [SSH client \(p. 614\)](#)
- [AWS Systems Manager Session Manager](#)
- [Windows Subsystem for Linux \(p. 633\)](#)

General prerequisites for connecting to your instance

Before you connect to your Linux instance, verify the following general prerequisites:

- [Get information about your instance \(p. 612\)](#)
- [Enable inbound traffic to your instance \(p. 613\)](#)
- [Locate the private key and set the permissions \(p. 613\)](#)
- [\(Optional\) Get the instance fingerprint \(p. 614\)](#)

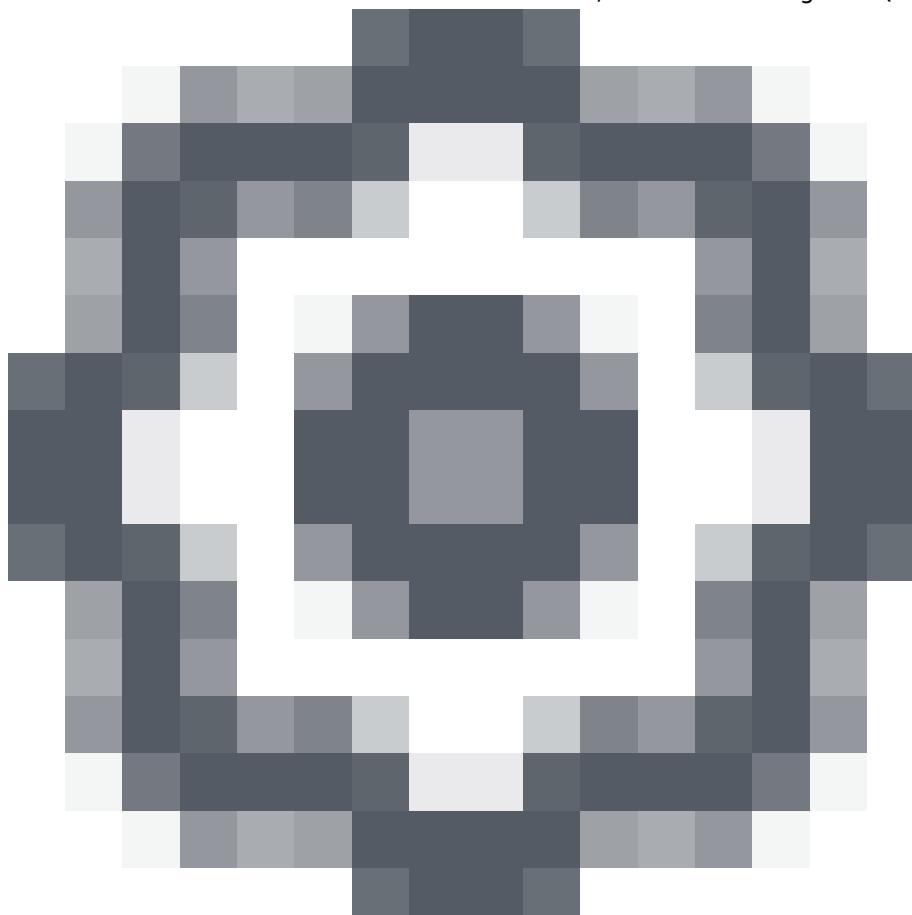

Get information about your instance

- **Get the ID of the instance.**

You can get the ID of your instance using the Amazon EC2 console (from the **Instance ID** column). If you prefer, you can use the [describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) command.

- **Get the public DNS name of the instance.**

You can get the public DNS for your instance using the Amazon EC2 console. Check the **Public IPv4 DNS** column. If this column is hidden, choose the settings icon (

) in the top-right

corner of the screen and select **Public IPv4 DNS**. If you prefer, you can use the [describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) command.

- **(IPv6 only) Get the IPv6 address of the instance.**

If you've assigned an IPv6 address to your instance, you can optionally connect to the instance using its IPv6 address instead of a public IPv4 address or public IPv4 DNS hostname. Your local computer must have an IPv6 address and must be configured to use IPv6. You can get the IPv6 address of your instance using the Amazon EC2 console. Check the **IPv6 IPs** field. If you prefer, you can use the

[describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) command. For more information about IPv6, see [IPv6 addresses \(p. 1039\)](#).

- **Get the user name for your instance.**

You can connect to your instance using the user name for your user account or the default user name for the AMI that you used to launch your instance.

- **Get the user name for your user account.**

For more information about how to create a user account, see [Manage user accounts on your Amazon Linux instance \(p. 675\)](#).

- **Get the default user name for the AMI that you used to launch your instance:**

- For Amazon Linux 2 or the Amazon Linux AMI, the user name is `ec2-user`.
- For a CentOS AMI, the user name is `centos` or `ec2-user`.
- For a Debian AMI, the user name is `admin`.
- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- For an Oracle AMI, the user name is `ec2-user`.
- For a Bitnami AMI, the user name is `bitnami`.
- Otherwise, check with the AMI provider.

Enable inbound traffic to your instance

- **Enable inbound SSH traffic from your IP address to your instance.**

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For more information, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).

Locate the private key and set the permissions

- **Locate the private key**

Get the fully-qualified path to the location on your computer of the `.pem` file for the key pair that you specified when you launched the instance. For more information, see [Identify the key pair that was specified at launch](#). If you can't find your private key file, see [Connect to your Linux instance if you lose your private key](#).

- **Set the permissions of your private key**

If you will use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 my-key-pair.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see [Error: Unprotected private key file \(p. 1719\)](#).

(Optional) Get the instance fingerprint

To protect yourself from man-in-the-middle attacks, you can verify the RSA key fingerprint when you connect to your instance. Verifying the fingerprint is useful if you've launched your instance from a public AMI from a third party.

First you get the instance fingerprint. Then, when you connect to the instance, you are prompted to verify the fingerprint. You can compare the fingerprint you obtained with the fingerprint displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to your instance.

Prerequisites for getting the instance fingerprint:

- To get the instance fingerprint, you must use the AWS CLI. For information about installing the AWS CLI, see [Installing the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.
- The instance must not be in the pending state. The fingerprint is available only after the first boot of the instance is complete.

To get the instance fingerprint

1. On your local computer (not on the instance), use the [get-console-output](#) (AWS CLI) command as follows to obtain the fingerprint:

```
aws ec2 get-console-output --instance-id instance_id --output text
```

2. Here is an example of what you should look for in the output. The exact output can vary by the operating system, AMI version, and whether you had AWS create the key.

```
ec2: #####

Connect to your Linux instance using SSH

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using an SSH client. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#). For more connection options, see [Connect to your Linux instance \(p. 611\)](#).

Prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Check your instance status

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the [Instances](#) page.

Get the public DNS name and user name to connect to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see [Prerequisites for connecting to your instance \(p. 611\)](#).

Locate the private key and set the permissions

To locate the private key that is required to connect to your instance, and to set the key permissions, see [Locate the private key and set the permissions \(p. 613\)](#).

Install an SSH client on your local computer as needed

Your local computer might have an SSH client installed by default. You can verify this by typing `ssh` at the command line. If your computer doesn't recognize the command, you can install an SSH client.

- Recent versions of Windows Server 2019 and Windows 10 - OpenSSH is included as an installable component. For more information, see [OpenSSH in Windows](#).
- Earlier versions of Windows - Download and install OpenSSH. For more information, see [Win32-OpenSSH](#).
- Linux and macOS X - Download and install OpenSSH. For more information, see <https://www.openssh.com>.

Connect to your Linux instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

To connect to your instance using SSH

- In a terminal window, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (`.pem`), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set the permissions \(p. 613\)](#) and [Get information about your instance \(p. 612\)](#). To connect to your instance, use one of the following commands.

- (Public DNS) To connect using your instance's public DNS name, enter the following command.

```
ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-public-dns-name
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.

```
ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-IPv6-address
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)'  
can't be established.  
ECDSA key fingerprint is 14UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.  
Are you sure you want to continue connecting (yes/no)?
```

- (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint \(p. 614\)](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
- Enter **yes**.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to the
list of known hosts.
```

Transfer files to Linux instances using an SCP client

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- **Verify the general prerequisites for transferring files to your instance.**

The general prerequisites for transferring files to an instance are the same as the general prerequisites for connecting to an instance. For more information, see [General prerequisites for connecting to your instance \(p. 611\)](#).

- **Install an SCP client**

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see <https://www.openssh.com>.

The following procedure steps you through using SCP to transfer a file using the instance's public DNS name, or the IPv6 address if your instance has one.

To use SCP to transfer files between your computer and your instance

1. Determine the location of the source file on your computer and the destination path on the instance. In the following examples, the name of the private key file is `my-key-pair.pem`, the file to transfer is `my-file.txt`, the user name for the instance is `ec2-user`, the public DNS name of the instance is `my-instance-public-dns-name`, and the IPv6 address of the instance is `my-instance-IPv6-address`.
 - (Public DNS) To transfer a file to the destination on the instance, enter the following command from your computer.

```
scp -i /path/my-key-pair.pem /path/my-file.txt ec2-user@my-instance-public-dns-
name:path/
```

- (IPv6) To transfer a file to the destination on the instance if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/my-key-pair.pem /path/my-file.txt ec2-user@[my-instance-IPv6-
address\]:path/
```

2. If you haven't already connected to the instance using SSH, you see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)'
can't be established.
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.
Are you sure you want to continue connecting (yes/no)?
```

(Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see [\(Optional\) Get the instance fingerprint \(p. 614\)](#).

Enter **yes**.

3. If the transfer is successful, the response is similar to the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)
to the list of known hosts.
my-file.txt                                100%   480      24.4KB/s  00:00
```

4. To transfer a file in the other direction (from your Amazon EC2 instance to your computer), reverse the order of the host parameters. For example, you can transfer `my-file.txt` from your EC2 instance to the a destination on your local computer as `my-file2.txt`, as shown in the following examples.

- (Public DNS) To transfer a file to a destination on your computer, enter the following command from your computer.

```
scp -i /path/my-key-pair.pem ec2-user@my-instance-public-dns-name:path/my-file.txt
path/my-file2.txt
```

- (IPv6) To transfer a file to a destination on your computer if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/my-key-pair.pem ec2-user@[my-instance-IPv6-address\]:path/my-file.txt
path/my-file2.txt
```

Troubleshoot

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

Connect to your Linux instance using EC2 Instance Connect

Amazon EC2 Instance Connect provides a simple and secure way to connect to your Linux instances using Secure Shell (SSH). With EC2 Instance Connect, you use AWS Identity and Access Management (IAM) [policies](#) and [principals](#) to control SSH access to your instances, removing the need to share and manage SSH keys. All connection requests using EC2 Instance Connect are [logged to AWS CloudTrail so that you can audit connection requests \(p. 1020\)](#).

You can use EC2 Instance Connect to connect to your instances using the Amazon EC2 console (browser-based client), the Amazon EC2 Instance Connect CLI, or the SSH client of your choice.

When you connect to an instance using EC2 Instance Connect, the Instance Connect API pushes a one-time-use SSH public key to the [instance metadata \(p. 726\)](#) where it remains for 60 seconds. An IAM policy attached to your IAM user authorizes your IAM user to push the public key to the instance metadata. The SSH daemon uses `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, which are configured when Instance Connect is installed, to look up the public key from the instance metadata for authentication, and connects you to the instance.

You can use EC2 Instance Connect to connect to instances that have public or private IP addresses. For more information, see [Connect using EC2 Instance Connect \(p. 624\)](#).

Contents

- [Set up EC2 Instance Connect \(p. 618\)](#)
- [Connect using EC2 Instance Connect \(p. 624\)](#)
- [Uninstall EC2 Instance Connect \(p. 627\)](#)

Tip

If you are connecting to a Linux instance from a local computer running Windows, see the following documentation instead:

- [Connect to your Linux instance from Windows using PuTTY \(p. 627\)](#)
- [Connect to your Linux instance using SSH \(p. 614\)](#)
- [Connect to your Linux instance from Windows using Windows Subsystem for Linux \(p. 633\)](#)

Set up EC2 Instance Connect

To use EC2 Instance Connect to connect to an instance, you need to configure every instance that will support using Instance Connect (this is a one-time requirement for each instance), and you need to grant permission to every IAM principal that will use Instance Connect. After completing the following setup tasks, you can [connect to your instance using EC2 Instance Connect \(p. 624\)](#).

Tasks to set up EC2 Instance Connect

- [Task 1: Configure network access to an instance \(p. 619\)](#)
- [Task 2: \(Conditional\) Install EC2 Instance Connect on an instance \(p. 619\)](#)
- [Task 3: \(Optional\) Install the EC2 Instance Connect CLI on your computer \(p. 622\)](#)
- [Task 4: Configure IAM permissions for EC2 Instance Connect \(p. 622\)](#)

For more information about setting up EC2 Instance Connect, see [Securing your bastion hosts with Amazon EC2 Instance Connect](#).

Limitations

- You can install EC2 Instance Connect on the following supported Linux distributions:
 - Amazon Linux 2 (any version)
 - Ubuntu 16.04 or later
- If you configured the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` settings for SSH authentication, the EC2 Instance Connect installation will not update them. As a result, you cannot use Instance Connect.

Prerequisites for installing EC2 Instance Connect

- **Verify the general prerequisites for connecting to your instance using SSH.**

For more information, see [General prerequisites for connecting to your instance \(p. 611\)](#).

- **Install an SSH client on your local computer.**

Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing `ssh` at the command line. If your local computer doesn't recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X, see <http://www.openssh.com>. For information about installing an SSH client on Windows 10, see [OpenSSH in Windows](#).

- **Install the AWS CLI on your local computer.**

To configure the IAM permissions, you must use the AWS CLI. For more information about installing the AWS CLI, see [Installing the AWS CLI in the AWS Command Line Interface User Guide](#).

- **[Ubuntu] Install the AWS CLI on your instance.**

To install EC2 Instance Connect on an Ubuntu instance, you must use the AWS CLI on the instance. For more information about installing the AWS CLI, see [Installing the AWS CLI in the AWS Command Line Interface User Guide](#).

Task 1: Configure network access to an instance

You must configure the following network access so that your users can connect to your instance using EC2 Instance Connect:

- If your users will access your instance over the internet, then your instance must have a public IP address and be in a public subnet. For more information, see [Enable internet access](#) in the *Amazon VPC User Guide*.
- If your users will access your instance through the instance's private IP address, then you must establish private network connectivity to your VPC, such as by using AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering, so that your users can reach the instance's private IP address.
- Ensure that the security group associated with your instance [allows inbound SSH traffic \(p. 1308\)](#) on port 22 from your IP address or from your network. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch wizard allows incoming SSH traffic by default. For more information, see [Authorize inbound traffic for your Linux instances \(p. 1307\)](#).
- (Amazon EC2 console browser-based client) Ensure that the security group associated with your instance allows inbound SSH traffic from the IP address range for this service. To identify the address range, download the JSON file provided by AWS and filter for the subset for EC2 Instance Connect, using `EC2_INSTANCE_CONNECT` as the service value. For more information about downloading the JSON file and filtering by service, see [AWS IP address ranges](#) in the *Amazon Web Services General Reference*.

Task 2: (Conditional) Install EC2 Instance Connect on an instance

You can skip this task if you used one of the following AMIs to launch your instance because they come preinstalled with EC2 Instance Connect:

- Amazon Linux 2 2.0.20190618 or later
- Ubuntu 20.04 or later

For earlier versions of these AMIs, you must install Instance Connect on every instance that will support connecting using Instance Connect.

Installing Instance Connect configures the SSH daemon on the instance. The procedure for installing Instance Connect is different for instances launched using Amazon Linux 2 and Ubuntu.

Amazon Linux 2

To install EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH.

Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is `ec2-user`.

For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance using SSH \(p. 614\)](#).

2. Install the EC2 Instance Connect package on your instance.

For Amazon Linux 2, use the **yum install** command.

```
[ec2-user ~]$ sudo yum install ec2-instance-connect
```

You should see four new scripts in the /opt/aws/bin/ folder:

```
eic_curlAuthorizedKeys  
eic_harvestHostkeys  
eic_parseAuthorizedKeys  
eic_runAuthorizedKeys
```

3. (Optional) Verify that Instance Connect was successfully installed on your instance.

Use the **sudo less** command to check that the /etc/ssh/sshd_config file was correctly updated as follows:

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config
```

Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines in the /etc/ssh/sshd_config file contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_runAuthorizedKeys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_runAuthorizedKeys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

Note

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the Instance Connect installation will not change the values and you will not be able to use Instance Connect.

Ubuntu

To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later

1. Connect to your instance using SSH.

Use the SSH key pair that was assigned to your instance when you launched it and use the default user name of the AMI that you used to launch your instance. For an Ubuntu AMI, the user name is `ubuntu`.

If your instance was launched using Ubuntu, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance using SSH \(p. 614\)](#).

2. (Optional) Ensure your instance has the latest Ubuntu AMI.

For Ubuntu, use the following commands to update all the packages on your instance.

```
ubuntu:~$ sudo apt-get update
```

```
ubuntu:~$ sudo apt-get upgrade
```

3. Install the Instance Connect package on your instance.

For Ubuntu, use the `sudo apt-get` command.

```
ubuntu:~$ sudo apt-get install ec2-instance-connect
```

You should see four new scripts in the `/usr/share/ec2-instance-connect/` folder:

```
eic_curlAuthorizedKeys  
eic_harvestHostkeys  
eic_parseAuthorizedKeys  
eic_runAuthorizedKeys
```

4. (Optional) Verify that Instance Connect was successfully installed on your instance.

Use the `sudo less` command to check that the `/lib/systemd/system/ssh.service.d/ec2-instance-connect.conf` was correctly updated as follows:

```
ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines in the `/lib/systemd/system/ssh.service.d/ec2-instance-connect.conf` file contain the following values:

```
AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_run_authorized_keys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

Note

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the Instance Connect installation will not change the values and you will not be able to use Instance Connect.

For more information about the EC2 Instance Connect package, see [aws/aws-ec2-instance-connect-config](#) on the GitHub website.

Task 3: (Optional) Install the EC2 Instance Connect CLI on your computer

The EC2 Instance Connect CLI provides a simplified experience to connect to EC2 instances through a single command, `ssh instance_id`. For more information, see [Connect using the EC2 Instance Connect CLI \(p. 625\)](#).

Note

There is no need to install the EC2 Instance Connect CLI if users will only use the Amazon EC2 console (browser-based client) or an SSH client to connect to an instance.

To install the EC2 Instance Connect CLI package

Use `pip` to install the `ec2instanceconnectcli` package. For more information, see [aws/aws-ec2-instance-connect-cli](#) on the GitHub website, and <https://pypi.org/project/ec2instanceconnectcli/> on the Python Package Index (PyPI) website.

```
$ pip install ec2instanceconnectcli
```

Task 4: Configure IAM permissions for EC2 Instance Connect

For your IAM principals to connect to an instance using EC2 Instance Connect, you must grant them permission to push the public key to the instance. You grant them the permission by creating an IAM policy and attaching the policy to the IAM principals that require the permission. For more information, see [Actions, resources, and condition keys for Amazon EC2 Instance Connect](#).

The following instructions explain how to create the policy and attach it to an IAM user using the AWS CLI. The same policy could be applied to other IAM principals, such as IAM roles. For instructions that use the AWS Management Console, see [Creating IAM policies \(console\)](#), [Adding permissions by attaching policies directly to the user](#), and [Creating IAM roles](#) in the *IAM User Guide*.

To grant an IAM principal permission for EC2 Instance Connect (AWS CLI)

1. Create a JSON policy document that includes the following:

- The `ec2-instance-connect:SendSSHPublicKey` action. This grants an IAM principal permission to push the public key to an instance. With `ec2-instance-connect:SendSSHPublicKey`, consider restricting access to specific EC2 instances. Otherwise, all IAM principals with this permission can connect to all EC2 instances. You can also restrict access by specifying resource ARNs or by using resource tags as [condition keys](#).
- The `ec2:osuser` condition. This specifies the name of the OS user that can push the public key to an instance. Use the default user name for the AMI that you used to launch the instance. The default user name for Amazon Linux 2 is `ec2-user`, and for Ubuntu it's `ubuntu`.
- The `ec2:DescribeInstances` action. This is required when using the EC2 Instance Connect CLI because the wrapper calls this action. IAM principals might already have permission to call this action from another policy.

The following is an example policy document. You can omit the statement for the `ec2:DescribeInstances` action if your users will only use an SSH client to connect to your instances. You can replace the specified instances in `Resource` with the wildcard `*` to grant users access to all EC2 instances using EC2 Instance Connect.

```
{  
    "Version": "2012-10-17",  
    "Statement": [
```

```
"Statement": [
    {
        "Effect": "Allow",
        "Action": "ec2-instance-connect:SendSSHPublicKey",
        "Resource": [

            "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
        ],
        "Condition": {
            "StringEquals": {
                "ec2:osuser": "ami-username"
            }
        }
    },
    {
        "Effect": "Allow",
        "Action": "ec2:DescribeInstances",
        "Resource": "*"
    }
]
```

The preceding policy allows access to specific instances, identified by their instance ID. Alternatively, you can use resource tags to control access to an instance. Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows an IAM user to access an instance only if that instance has a resource tag with key=tag-key and value=tag-value. For more information about using tags to control access to your AWS resources, see [Controlling access to AWS resources](#) in the *IAM User Guide*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2-instance-connect:SendSSHPublicKey",
            "Resource": "arn:aws:ec2:region:account-id:instance/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/tag-key": "tag-value"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeInstances",
            "Resource": "*"
        }
    ]
}
```

2. Use the [create-policy](#) command to create a new managed policy, and specify the JSON document that you created to use as the content for the new policy.

```
$ aws iam create-policy --policy-name my-policy --policy-document file://JSON-file-name
```

3. Use the [attach-user-policy](#) command to attach the managed policy to the specified IAM user. For the **--user-name** parameter, specify the friendly name (not the ARN) of the IAM user.

```
$ aws iam attach-user-policy --policy-arn arn:aws:iam::account-id:policy/my-policy --user-name IAM-friendly-name
```

Connect using EC2 Instance Connect

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect.

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#) and [How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?](#).

Topics

- [Limitations \(p. 624\)](#)
- [Prerequisites \(p. 624\)](#)
- [Connect using EC2 Instance Connect \(p. 624\)](#)

Limitations

- Supported Linux distributions:
 - Amazon Linux 2 (any version)
 - Ubuntu 16.04 or later
- Supported in all AWS Regions except Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), China (Beijing), China (Ningxia), Europe (Milan), and Middle East (Bahrain).
- To connect using the Amazon EC2 console (browser-based client), the instance must have a public IPv4 address.
- If the instance does not have a public IP address, you can connect to the instance over a private network using an SSH client or the EC2 Instance Connect CLI. For example, you can connect from within the same VPC or through a VPN connection, transit gateway, or AWS Direct Connect.
- EC2 Instance Connect does not support connecting using an IPv6 address.

Prerequisites

- **Install EC2 Instance Connect on your instance.**

For more information, see [Set up EC2 Instance Connect \(p. 618\)](#).

- **(Optional) Install an SSH client on your local computer.**

There is no need to install an SSH client if users only use the Amazon EC2 console (browser-based client) or the EC2 Instance Connect CLI to connect to an instance. Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing `ssh` at the command line. If your local computer doesn't recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X, see <http://www.openssh.com>. For information about installing an SSH client on Windows 10, see [OpenSSH in Windows](#).

- **(Optional) Install the EC2 Instance Connect CLI on your local computer.**

There is no need to install the EC2 Instance Connect CLI if users only use the Amazon EC2 console (browser-based client) or an SSH client to connect to an instance. For more information, see [Task 3: \(Optional\) Install the EC2 Instance Connect CLI on your computer \(p. 622\)](#). This connection method works for instances with public IP addresses.

Connect using EC2 Instance Connect

Options

- [Connect using the Amazon EC2 console \(browser-based client\) \(p. 625\)](#)
- [Connect using the EC2 Instance Connect CLI \(p. 625\)](#)

- [Connect using your own key and SSH client \(p. 626\)](#)

[Connect using the Amazon EC2 console \(browser-based client\)](#)

You can connect to an instance using the Amazon EC2 console (browser-based client) by selecting the instance from the console and choosing to connect using EC2 Instance Connect. Instance Connect handles the permissions and provides a successful connection.

To connect to your instance using the browser-based client from the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. Choose **EC2 Instance Connect**.
5. Verify the user name and choose **Connect** to open a terminal window.

[Connect using the EC2 Instance Connect CLI](#)

You can connect to an instance using the EC2 Instance Connect CLI by providing only the instance ID, while the Instance Connect CLI performs the following three actions in one call: it generates a one-time-use SSH public key, pushes the key to the instance where it remains for 60 seconds, and connects the user to the instance. You can use basic SSH/SFTP commands with the Instance Connect CLI.

This connection method works for instances with public and private IP addresses. When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as [AWS Direct Connect](#), [AWS Site-to-Site VPN](#), or [VPC peering](#).

Note

–*i* is not supported when using **mssh**. When using the **mssh** command to connect to your instance, you do not need to specify any kind of identity file because Instance Connect manages the key pair.

Amazon Linux 2

To connect to an instance using the EC2 Instance Connect CLI

Use the **mssh** command with the instance ID as follows. You do not need to specify the user name for the AMI.

```
$ mssh i-001234a4bf70dec41EXAMPLE
```

Ubuntu

To connect to an instance using the EC2 Instance Connect CLI

Use the **mssh** command with the instance ID and the default user name for the Ubuntu AMI as follows. You must specify the user name for the AMI or you get the following error: Authentication failed.

```
$ mssh ubuntu@i-001234a4bf70dec41EXAMPLE
```

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

Requirements

- Requirements for key pairs
 - Supported types: RSA (OpenSSH and SSH2) and ED25519
 - Supported lengths: 2048 and 4096
- For more information, see [Create a key pair using a third-party tool and import the public key to Amazon EC2 \(p. 1313\)](#).
- When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as [AWS Direct Connect](#), [AWS Site-to-Site VPN](#), or [VPC peering](#).

To connect to your instance using your own key and any SSH client

1. (Optional) Generate new SSH private and public keys

You can generate new SSH private and public keys, `my_key` and `my_key.pub`, using the following command:

```
$ ssh-keygen -t rsa -f my_key
```

2. Push your SSH public key to the instance

Use the `send-ssh-public-key` command to push your SSH public key to the instance. If you launched your instance using Amazon Linux 2, the default user name for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default user name for the AMI is `ubuntu`.

The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`.

```
$ aws ec2-instance-connect send-ssh-public-key \
--instance-id i-001234a4bf70dec41EXAMPLE \
--availability-zone us-west-2b \
--instance-os-user ec2-user \
--ssh-public-key file://my_key.pub
```

3. Connect to the instance using your private key

Use the `ssh` command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default user name for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the `ssh` config and the specified key are used for the connection.

```
$ ssh -o "IdentitiesOnly=yes" -i my_key ec2-
user@ec2-198-51-100-1.compute-1.amazonaws.com
```

Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your instance and uninstall the `ec2-instance-connect` package that you installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the `sshd` configuration. If you modified the `sshd` configuration after installing EC2 Instance Connect, you must update it manually.

Amazon Linux 2

You can uninstall EC2 Instance Connect on Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

To uninstall EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Amazon Linux 2 AMI, which is `ec2-user`.

For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the `yum` command.

```
[ec2-user ~]$ sudo yum remove ec2-instance-connect
```

Ubuntu

To uninstall EC2 Instance Connect on an instance launched with an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Ubuntu AMI, which is `ubuntu`.

For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the `apt-get` command.

```
ubuntu:~$ sudo apt-get remove ec2-instance-connect
```

Connect to your Linux instance from Windows using PuTTY

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using PuTTY, a free SSH client for Windows. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

Prerequisites

Before you connect to your Linux instance using PuTTY, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the **Instances** page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see [General prerequisites for connecting to your instance \(p. 611\)](#).

Install PuTTY on your local computer

Download and install PuTTY from the [PuTTY download page](#). If you already have an older version of PuTTY installed, we recommend that you download the latest version. Be sure to install the entire suite.

Convert your private key using PuTTYgen

Locate the private key (.pem file) for the key pair that you specified when you launched the instance. Convert the .pem file to a .ppk file for use with PuTTY. For more information, follow the steps in the next section.

Convert your private key using PuTTYgen

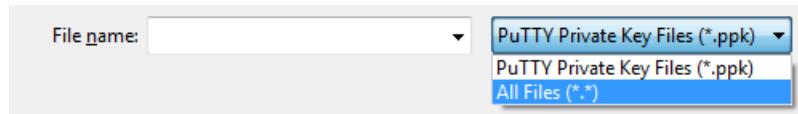

PuTTY does not natively support the private key format for SSH keys. PuTTY provides a tool named PuTTYgen, which converts keys to the required format for PuTTY. You must convert your private key (.pem file) into this format (.ppk file) as follows in order to connect to your instance using PuTTY.

To convert your private key

1. From the **Start** menu, choose **All Programs, PuTTY, PuTTYgen**.
2. Under **Type of key to generate**, choose **RSA**. If your version of PuTTYgen does not include this option, choose **SSH-2 RSA**.

3. Choose **Load**. By default, PuTTYgen displays only files with the extension **.ppk**. To locate your **.pem** file, choose the option to display files of all types.

4. Select your **.pem** file for the key pair that you specified when you launched your instance and choose **Open**. PuTTYgen displays a notice that the **.pem** file was successfully imported. Choose **OK**.
5. To save the key in the format that PuTTY can use, choose **Save private key**. PuTTYgen displays a warning about saving the key without a passphrase. Choose **Yes**.

Note

A passphrase on a private key is an extra layer of protection. Even if your private key is discovered, it can't be used without the passphrase. The downside to using a passphrase is that it makes automation harder because human intervention is needed to log on to an instance, or to copy files to an instance.

- Specify the same name for the key that you used for the key pair (for example, `my-key-pair`) and choose **Save**. PuTTY automatically adds the `.ppk` file extension.

Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.

Connect to your Linux instance

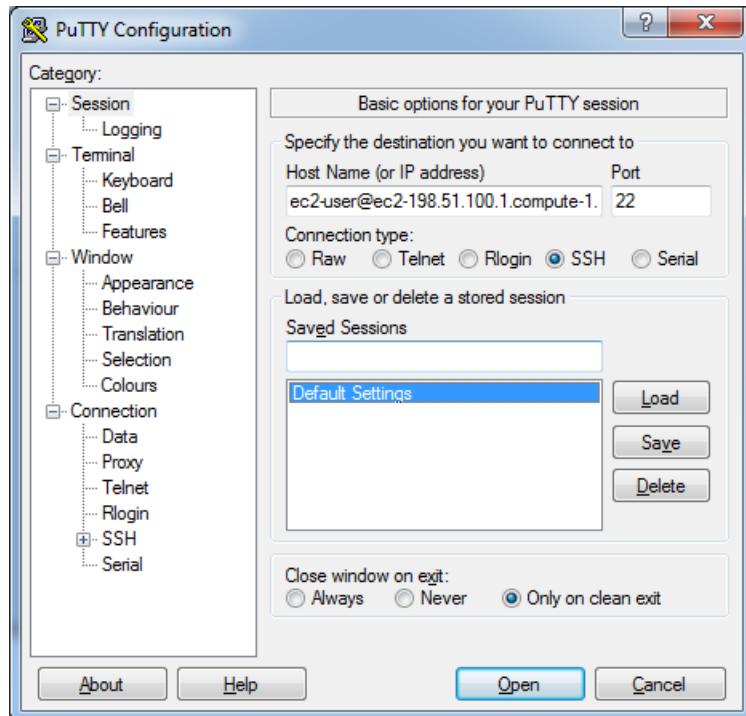

Use the following procedure to connect to your Linux instance using PuTTY. You need the `.ppk` file that you created for your private key. For more information, see [Convert your private key using PuTTYgen \(p. 628\)](#) in the preceding section. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

To connect to your instance using PuTTY

- Start PuTTY (from the **Start** menu, choose **All Programs, PuTTY, PuTTY**).
- In the **Category** pane, choose **Session** and complete the following fields:
 - In the **Host Name** box, do one of the following:
 - (Public DNS) To connect using your instance's public DNS name, enter `my-instance-user-name@my-instance-public-dns-name`.
 - (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter `my-instance-user-name@my-instance-IPv6-address`.
 - Ensure that the **Port** value is 22.
 - Under **Connection type**, select **SSH**.

For information about how to get the user name for your instance, and the public DNS name or IPv6 address of your instance, see [Get information about your instance \(p. 612\)](#).

- Under **Connection type**, select **SSH**.

3. (Optional) You can configure PuTTY to automatically send 'keepalive' data at regular intervals to keep the session active. This is useful to avoid disconnecting from your instance due to session inactivity. In the **Category** pane, choose **Connection**, and then enter the required interval in the **Seconds between keepalives** field. For example, if your session disconnects after 10 minutes of inactivity, enter 180 to configure PuTTY to send keepalive data every 3 minutes.
4. In the **Category** pane, expand **Connection**, expand **SSH**, and then choose **Auth**. Complete the following:
 - a. Choose **Browse**.
 - b. Select the **.ppk** file that you generated for your key pair and choose **Open**.
 - c. (Optional) If you plan to start this session again later, you can save the session information for future use. Under **Category**, choose **Session**, enter a name for the session in **Saved Sessions**, and then choose **Save**.
 - d. Choose **Open**.
5. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host to which you are connecting.
 - a. (Optional) Verify that the fingerprint in the security alert dialog box matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint \(p. 614\)](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
 - b. Choose **Yes**. A window opens and you are connected to your instance.

Note

If you specified a passphrase when you converted your private key to PuTTY's format, you must provide that passphrase when you log in to the instance.

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

Transfer files to your Linux instance using the PuTTY Secure Copy client

The PuTTY Secure Copy client (PSCP) is a command line tool that you can use to transfer files between your Windows computer and your Linux instance. If you prefer a graphical user interface (GUI), you can use an open source GUI tool named WinSCP. For more information, see [Transfer files to your Linux instance using WinSCP \(p. 631\)](#).

To use PSCP, you need the private key you generated in [Convert your private key using PuTTYgen \(p. 628\)](#). You also need the public DNS name of your Linux instance, or the IPv6 address if your instance has one.

The following example transfers the file `Sample_file.txt` from the `C:\` drive on a Windows computer to the `my-instance-user-name` home directory on an Amazon Linux instance. To transfer a file, use one of the following commands.

- (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
pscp -i C:\\path\\my-key-pair.ppk C:\\path\\Sample_file.txt my-instance-user-name@my-instance-public-dns-name:/home/my-instance-user-name/Sample_file.txt
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer a file using your instance's IPv6 address, enter the following command. The IPv6 address must be enclosed in square brackets ([]).

```
pscp -i C:\\path\\my-key-pair.ppk C:\\path\\Sample_file.txt my-instance-user-name@[my-instance-IPv6-address]:/home/my-instance-user-name/Sample_file.txt
```

Transfer files to your Linux instance using WinSCP

WinSCP is a GUI-based file manager for Windows that allows you to upload and transfer files to a remote computer using the SFTP, SCP, FTP, and FTPS protocols. WinSCP allows you to drag and drop files from your Windows computer to your Linux instance or synchronize entire directory structures between the two systems.

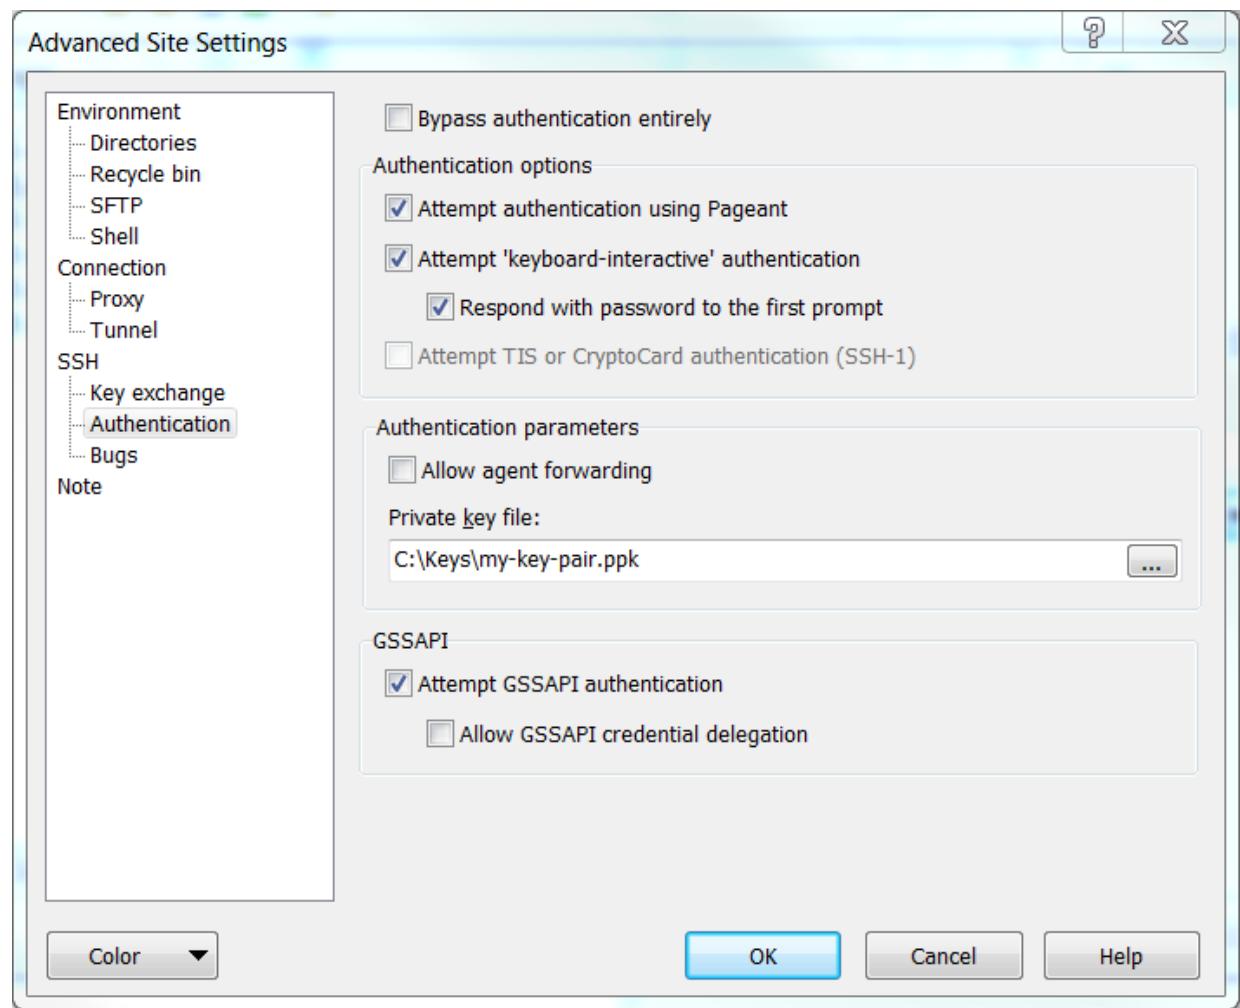

Requirements

- You must have the private key that you generated in [Convert your private key using PuTTYgen \(p. 628\)](#).
- You must have the public DNS name of your Linux instance.
- Your Linux instance must have `scp` installed. For some operating systems, you install the `openssh-clients` package. For others, such as the Amazon ECS-optimized AMI, you install the `scp` package. Check the documentation for your Linux distribution.

To connect to your instance using WinSCP

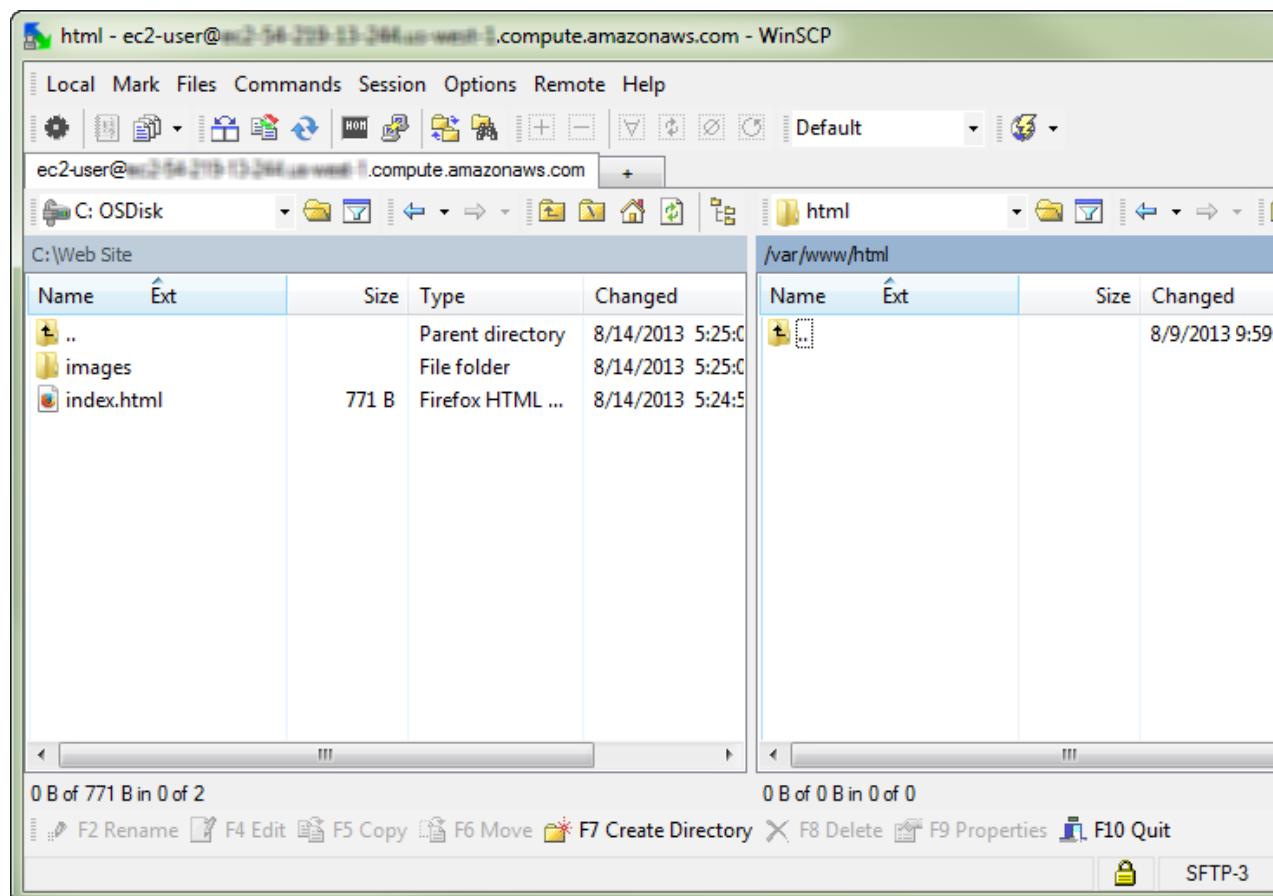

1. Download and install WinSCP from <http://winscp.net/eng/download.php>. For most users, the default installation options are OK.
2. Start WinSCP.
3. At the **WinSCP login** screen, for **Host name**, enter one of the following:
 - (Public DNS or IPv4 address) To log in using your instance's public DNS name or public IPv4 address, enter the public DNS name or public IPv4 address for your instance.
 - (IPv6) Alternatively, if your instance has an IPv6 address, to log in using your instance's IPv6 address, enter the IPv6 address for your instance.
4. For **User name**, enter the default user name for your AMI.
 - For Amazon Linux 2 or the Amazon Linux AMI, the user name is `ec2-user`.
 - For a CentOS AMI, the user name is `centos` or `ec2-user`.
 - For a Debian AMI, the user name is `admin`.
 - For a Fedora AMI, the user name is `fedora` or `ec2-user`.
 - For a RHEL AMI, the user name is `ec2-user` or `root`.
 - For a SUSE AMI, the user name is `ec2-user` or `root`.
 - For an Ubuntu AMI, the user name is `ubuntu`.
 - For an Oracle AMI, the user name is `ec2-user`.
 - For a Bitnami AMI, the user name is `bitnami`.
 - Otherwise, check with the AMI provider.
5. Specify the private key for your instance. For **Private key**, enter the path to your private key, or choose the "..." button to browse for the file. To open the advanced site settings, for newer versions of WinSCP, choose **Advanced**. To find the **Private key file** setting, under **SSH**, choose **Authentication**.

Here is a screenshot from WinSCP version 5.9.4:

WinSCP requires a PuTTY private key file (.ppk). You can convert a .pem security key file to the .ppk format using PuTTYgen. For more information, see [Convert your private key using PuTTYgen \(p. 628\)](#).

6. (Optional) In the left panel, choose **Directories**. For **Remote directory**, enter the path for the directory to which to add files. To open the advanced site settings for newer versions of WinSCP, choose **Advanced**. To find the **Remote directory** setting, under **Environment**, choose **Directories**.
7. Choose **Login**. To add the host fingerprint to the host cache, choose **Yes**.

- After the connection is established, in the connection window your Linux instance is on the right and your local machine is on the left. You can drag and drop files between the remote file system and your local machine. For more information on WinSCP, see the project documentation at <http://winscp.net/eng/docs/start>.

If you receive an error that you cannot run SCP to start the transfer, verify that you installed `scp` on the Linux instance.

Connect to your Linux instance from Windows using Windows Subsystem for Linux

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance using a Linux distribution on the Windows Subsystem for Linux (WSL). WSL is a free download and enables you to run native Linux command line tools directly on Windows, alongside your traditional Windows desktop, without the overhead of a virtual machine.

By installing WSL, you can use a native Linux environment to connect to your Linux EC2 instances instead of using PuTTY or PuTTYgen. The Linux environment makes it easier to connect to your Linux instances because it comes with a native SSH client that you can use to connect to your Linux instances and change the permissions of the .pem key file. The Amazon EC2 console provides the SSH command for connecting to the Linux instance, and you can get verbose output from the SSH command for troubleshooting. For more information, see the [Windows Subsystem for Linux Documentation](#).

Note

After you've installed the WSL, all the prerequisites and steps are the same as those described in [Connect to your Linux instance using SSH \(p. 614\)](#), and the experience is just like using native Linux.

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

Contents

- [Prerequisites \(p. 614\)](#)
- [Connect to your Linux instance using WSL \(p. 634\)](#)
- [Transfer files to Linux instances from Linux using SCP \(p. 635\)](#)
- [Uninstall WSL \(p. 637\)](#)

Prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the [Instances](#) page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see [General prerequisites for connecting to your instance \(p. 611\)](#).

Install the Windows Subsystem for Linux (WSL) and a Linux distribution on your local computer

Install the WSL and a Linux distribution using the instructions in the [Windows 10 Installation Guide](#). The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

Copy the private key from Windows to WSL

In a WSL terminal window, copy the `.pem` file (for the key pair that you specified when you launched the instance) from Windows to WSL. Note the fully-qualified path to the `.pem` file on WSL to use when connecting to your instance. For information about how to specify the path to your Windows hard drive, see [How do I access my C drive?](#). For more information about key pairs and Windows instances, see [Amazon EC2 key pairs and Windows instances](#).

```
cp /mnt/<Windows drive letter>/path/my-key-pair.pem ~/WSL-path/my-key-pair.pem
```

Connect to your Linux instance using WSL

Use the following procedure to connect to your Linux instance using the Windows Subsystem for Linux (WSL). If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance \(p. 1712\)](#).

To connect to your instance using SSH

1. In a terminal window, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (`.pem`), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set the permissions \(p. 613\)](#) and [Get information about your instance \(p. 612\)](#). To connect to your instance, use one of the following commands.

- (Public DNS) To connect using your instance's public DNS name, enter the following command.

```
ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-public-dns-name
```

- (IPv6) Alternatively, if your instance has an IPv6 address, you can connect to the instance using its IPv6 address. Specify the `ssh` command with the path to the private key (.pem) file, the appropriate user name, and the IPv6 address.

```
ssh -i /path/my-key-pair.pem my-instance-user-name@my-instance-IPv6-address
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)'  
can't be established.  
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.  
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint \(p. 614\)](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)  
to the list of known hosts.
```

Transfer files to Linux instances from Linux using SCP

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- **Verify the general prerequisites for transferring files to your instance.**

The general prerequisites for transferring files to an instance are the same as the general prerequisites for connecting to an instance. For more information, see [General prerequisites for connecting to your instance \(p. 611\)](#).

- **Install an SCP client**

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see <https://www.openssh.com>.

The following procedure steps you through using SCP to transfer a file. If you've already connected to the instance with SSH and have verified its fingerprints, you can start with the step that contains the SCP command (step 4).

To use SCP to transfer a file

1. Transfer a file to your instance using the instance's public DNS name. For example, if the name of the private key file is `my-key-pair`, the file to transfer is `SampleFile.txt`, the user name is `my-`

instance-user-name, and the public DNS name of the instance is my-instance-public-dns-name or the IPv6 address is my-instance-IPv6-address, use one the following commands to copy the file to the my-instance-user-name home directory.

- (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
scp -i /path/my-key-pair.pem /path/SampleFile.txt my-instance-user-name@my-instance-public-dns-name:~
```

- (IPv6) Alternatively, if your instance has an IPv6 address, you can transfer a file using the instance's IPv6 address. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/my-key-pair.pem /path/SampleFile.txt my-instance-user-name@[my-instance-IPv6-address]:~
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.  
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.  
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint \(p. 614\)](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
3. Enter **yes**.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.  
Sending file modes: C0644 20 SampleFile.txt  
Sink: C0644 20 SampleFile.txt  
SampleFile.txt 100% 20 0.0KB/s 00:00
```

If you receive a "bash: scp: command not found" error, you must first install **scp** on your Linux instance. For some operating systems, this is located in the **openssh-clients** package. For Amazon Linux variants, such as the Amazon ECS-optimized AMI, use the following command to install **scp**:

```
[ec2-user ~]$ sudo yum install -y openssh-clients
```

4. To transfer files in the other direction (from your Amazon EC2 instance to your local computer), reverse the order of the host parameters. For example, to transfer the **SampleFile.txt** file from your EC2 instance back to the home directory on your local computer as **SampleFile2.txt**, use one of the following commands on your local computer.
 - (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
scp -i /path/my-key-pair.pem my-instance-user-name@ec2-198-51-100-1.compute-1.amazonaws.com:~/SampleFile.txt ~/SampleFile2.txt
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer files in the other direction using the instance's IPv6 address, enter the following command.

```
scp -i /path/my-key-pair.pem my-instance-user-name@  
\[2001:db8:1234:1a00:9691:9503:25ad:1761\]:~/SampleFile.txt ~/SampleFile2.txt
```

Uninstall WSL

For information about uninstalling Windows Subsystem for Linux, see [How do I uninstall a WSL Distribution?](#).

Connect to your Linux instance using Session Manager

Session Manager is a fully managed AWS Systems Manager capability that lets you manage your Amazon EC2 instances through an interactive one-click browser-based shell or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run bash commands as you would through any other connection type. For more information about Session Manager, see [AWS Systems Manager Session Manager](#) in the [AWS Systems Manager User Guide](#).

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information and instructions, see [Setting up Session Manager](#).

To connect to a Linux instance using Session Manager using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For **Connection method**, choose **Session Manager**.
5. Choose **Connect**.

Troubleshooting

If you receive an error that you're not authorized to perform one or more Systems Manager actions (`ssm:command-name`), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information, see [Quickstart default IAM policies for Session Manager](#) in the [AWS Systems Manager User Guide](#).

Stop and start your instance

You can stop and start your instance if it has an Amazon EBS volume as its root device. The instance retains its instance ID, but can change as described in the [Overview \(p. 638\)](#) section.

When you stop an instance, we shut it down. We don't charge usage for a stopped instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes. Each time you start a stopped instance we charge a minimum of one minute for usage. After one minute, we charge only for the seconds you use. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage.

While the instance is stopped, you can treat its root volume like any other volume, and modify it (for example, repair file system problems or update software). You just detach the volume from the stopped instance, attach it to a running instance, make your changes, detach it from the running instance, and then reattach it to the stopped instance. Make sure that you reattach it using the storage device name that's specified as the root device in the block device mapping for the instance.

If you decide that you no longer need an instance, you can terminate it. As soon as the state of an instance changes to **shutting-down** or **terminated**, we stop charging for that instance. For more

information, see [Terminate your instance \(p. 661\)](#). If you'd rather hibernate the instance, see [Hibernate your On-Demand Linux instance \(p. 640\)](#). For more information, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

Overview

You can only stop an Amazon EBS-backed instance. To verify the root device type of your instance, describe the instance and check whether the device type of its root volume is `ebs` (Amazon EBS-backed instance) or `instance store` (instance store-backed instance). For more information, see [Determine the root device type of your AMI \(p. 107\)](#).

When you stop a running instance, the following happens:

- The instance performs a normal shutdown and stops running; its status changes to `stopping` and then `stopped`.
- Any Amazon EBS volumes remain attached to the instance, and their data persists.
- Any data stored in the RAM of the host computer or the instance store volumes of the host computer is gone.
- In most cases, the instance is migrated to a new underlying host computer when it's started (though in some cases, it remains on the current host).
- The instance retains its private IPv4 addresses and any IPv6 addresses when stopped and started. We release the public IPv4 address and assign a new one when you start it.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses associated with a stopped instance. With EC2-Classic, an Elastic IP address is dissociated from your instance when you stop it. For more information, see [EC2-Classic \(p. 1209\)](#).
- When you stop and start a Windows instance, the EC2Config service performs tasks on the instance, such as changing the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see [Configuring a Windows instance using the EC2Config service](#) in the *Amazon EC2 User Guide for Windows Instances*.
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. For more information, see [Health Checks for Auto Scaling Instances](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you stop a ClassicLink instance, it's unlinked from the VPC to which it was linked. You must link the instance to the VPC again after starting it. For more information about ClassicLink, see [ClassicLink \(p. 1214\)](#).

For more information, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

You can modify the following attributes of an instance only when it is stopped:

- Instance type
- User data
- Kernel
- RAM disk

If you try to modify these attributes while the instance is running, Amazon EC2 returns the `IncorrectInstanceState` error.

What happens when you stop an instance

When an EC2 instance is stopped using the `stop-instances` command, the following is registered at the OS level:

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not shut down cleanly within a few minutes, a hard shutdown is performed.

By default, when you initiate a shutdown from an Amazon EBS-backed instance (for example, using the `shutdown` or `poweroff` command), the instance stops. You can change this behavior so that it terminates instead. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).

Using the `halt` command from an instance does not initiate a shutdown. If used, the instance does not terminate; instead, it places the CPU into `HLT` and the instance remains running.

Stop and start your instances

You can stop and start your Amazon EBS-backed instance using the console or the command line.

New console

To stop and start an Amazon EBS-backed instance using the console

1. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Instance state, Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. (Optional) While your instance is stopped, you can modify certain instance attributes. For more information, see [Modify a stopped instance \(p. 640\)](#).
6. To start the stopped instance, select the instance, and choose **Instance state, Start instance**.
7. It can take a few minutes for the instance to enter the `running` state.

Old console

To stop and start an Amazon EBS-backed instance using the console

1. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Actions, Instance State, Stop**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.

4. When prompted for confirmation, choose **Yes, Stop**. It can take a few minutes for the instance to stop.
5. (Optional) While your instance is stopped, you can modify certain instance attributes. For more information, see [Modify a stopped instance \(p. 640\)](#).
6. To start the stopped instance, select the instance, and choose **Actions, Instance State, Start**.
7. In the confirmation dialog box, choose **Yes, Start**. It can take a few minutes for the instance to enter the `running` state.

To stop and start an Amazon EBS-backed instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [stop-instances](#) and [start-instances](#) (AWS CLI)
- [Stop-EC2Instance](#) and [Start-EC2Instance](#) (AWS Tools for Windows PowerShell)

To run a controlled fault injection experiment

You can use AWS Fault Injection Simulator to test how your application responds when your instance is stopped and started. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Modify a stopped instance

You can change the instance type, user data, and EBS-optimization attributes of a stopped instance using the AWS Management Console or the command line interface. You can't use the AWS Management Console to modify the `DeleteOnTermination`, kernel, or RAM disk attributes.

To modify an instance attribute

- To change the instance type, see [Change the instance type \(p. 382\)](#).
- To change the user data for your instance, see [Work with instance user data \(p. 742\)](#).
- To enable or disable EBS-optimization for your instance, see [Modifying EBS-Optimization \(p. 1587\)](#).
- To change the `DeleteOnTermination` attribute of the root volume for your instance, see [Update the block device mapping of a running instance \(p. 1661\)](#). You are not required to stop the instance to change this attribute.

To modify an instance attribute using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Troubleshoot stopping your instance

If you have stopped your Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance \(p. 1723\)](#).

Hibernate your On-Demand Linux instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon

Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When you start your instance:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID

You can hibernate an instance only if it's [enabled for hibernation \(p. 650\)](#) and it meets the [hibernation prerequisites \(p. 642\)](#).

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

You're not charged for instance usage for a hibernated instance when it is in the stopped state. However, you are charged for instance usage while the instance is in the stopping state, while the contents of the RAM are transferred to the EBS root volume. (This is different from when you [stop an instance \(p. 637\)](#) without hibernating it.) You're not charged for data transfer. However, you are charged for storage of any EBS volumes, including storage for the RAM contents.

If you no longer need an instance, you can terminate it at any time, including when it is in a stopped (hibernated) state. For more information, see [Terminate your instance \(p. 661\)](#).

Note

For information about using hibernation on Windows instances, see [Hibernate Your Windows Instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

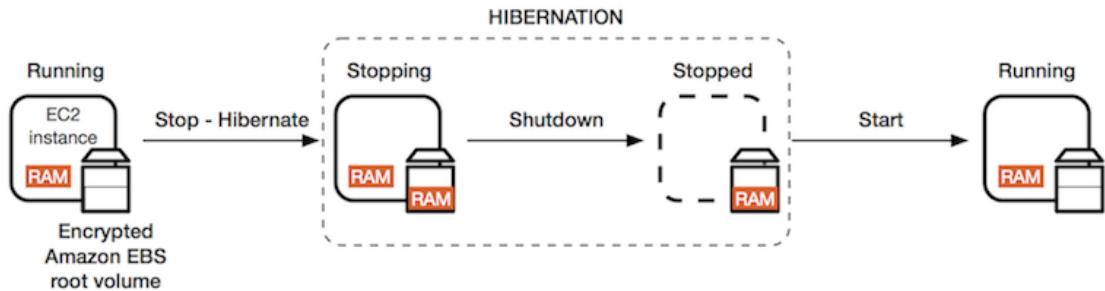

This topic describes how to hibernate On-Demand Instances (including those that may be covered by a Reserved Instance or a Capacity Reservation). For information about hibernating Spot Instances, see [Hibernate interrupted Spot Instances \(p. 477\)](#).

Overview of hibernation

The following diagram shows a basic overview of the hibernation process.

When you hibernate a running instance, the following happens:

- When you initiate hibernation, the instance moves to the stopping state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the stopped state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When you start the instance, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When you start the instance, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When you start the instance, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance. With EC2-Classic, an Elastic IP address is disassociated from your instance when you hibernate it. For more information, see [EC2-Classic \(p. 1209\)](#).
- When you hibernate a ClassicLink instance, it's unlinked from the VPC to which it was linked. You must link the instance to the VPC again after starting it. For more information, see [ClassicLink \(p. 1214\)](#).

For information about how hibernation differs from reboot, stop, and terminate, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

Hibernation prerequisites

To hibernate an On-Demand Instance, the following prerequisites must be in place:

- [Supported Linux AMIs \(p. 643\)](#)
- [Supported instance families \(p. 644\)](#)
- [Instance size \(p. 644\)](#)
- [Instance RAM size \(p. 644\)](#)
- [Root volume type \(p. 644\)](#)
- [EBS root volume size \(p. 644\)](#)
- [Supported EBS volume types \(p. 644\)](#)

- [EBS root volume encryption \(p. 645\)](#)
- [Enable hibernation at launch \(p. 645\)](#)
- [Purchasing options \(p. 645\)](#)

Supported Linux AMIs

Must be an HVM AMI that supports hibernation:

AMI	Xen - supported instance families only	Nitro - supported instance families only
Amazon Linux 2 AMI released 2019.08.29 or later	Supported	Supported
Amazon Linux AMI 2018.03 released 2018.11.16 or later	Supported	Supported
CentOS version 8 AMI* (Additional configuration (p. 647) is required)	Not supported	Supported
Fedora version 34 or later AMI* (Additional configuration (p. 648) is required)	Not supported	Supported
Red Hat Enterprise Linux (RHEL) 8 AMI* (Additional configuration (p. 648) is required)	Not supported	Supported
Ubuntu 20.04 LTS - Focal AMI released with serial number 20210820 or later †	Supported	Supported
Ubuntu 18.04 LTS - Bionic AMI released with serial number 20190722.1 or later †	Supported	Supported
Ubuntu 16.04 LTS - Xenial AMI † (Additional configuration (p. 649) is required)	Supported	Supported

* For CentOS, Fedora, and Red Hat Enterprise Linux, hibernation is supported on Nitro-based instances only.

† We recommend disabling KASLR on instances with Ubuntu 20.04 LTS – Focal, Ubuntu 18.04 LTS – Bionic, and Ubuntu 16.04 LTS – Xenial. For more information, see [Disable KASLR on an instance \(Ubuntu only\) \(p. 653\)](#).

To configure your own AMI to support hibernation, see [Configure an existing AMI to support hibernation \(p. 646\)](#).

Support for other versions of Ubuntu and other operating systems is coming soon.

For information about the supported Windows AMIs, see [Supported Windows AMIs in the Amazon EC2 User Guide for Windows Instances](#).

Supported instance families

- Xen: C3, C4, I3, M3, M4, R3, R4, T2
- Nitro: C5, C5d, M5, M5a, M5ad, M5d, R5, R5a, R5ad, R5d, T3, T3a

To see the available instance types that support hibernation in a specific Region

The available instance types vary by Region. To see the available instance types that support hibernation in a Region, use the [describe-instance-types](#) command with the `--region` parameter. Include the `--filters` parameter to scope the results to the instance types that support hibernation and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types --filters Name=hibernation-supported,Values=true --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Example output

```
c3.2xlarge
c3.4xlarge
c3.8xlarge
c3.large
c3.xlarge
c4.2xlarge
c4.4xlarge
c4.8xlarge
...
...
```

Instance size

Not supported for bare metal instances.

Instance RAM size

Must be less than 150 GB.

Root volume type

Must be an EBS volume, not an instance store volume.

EBS root volume size

Must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.

Supported EBS volume types

- General Purpose SSD (gp2 and gp3)
- Provisioned IOPS SSD (io1 and io2)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see [Amazon EBS volume types \(p. 1352\)](#).

EBS root volume encryption

To use hibernation, the root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Encryption by default \(p. 1545\)](#).
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs \(p. 203\)](#).
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see [Encrypt an unencrypted image during copy \(p. 207\)](#) and [Copy an AMI \(p. 182\)](#).

Enable hibernation at launch

You cannot enable hibernation on an existing instance (running or stopped). For more information, see [Enable hibernation for an instance \(p. 650\)](#).

Purchasing options

This feature is available for On-Demand Instances, including those that have a Reserved Instance billing discount applied to them. It is not available for Spot Instances. For information about hibernating a Spot Instance, see [Hibernate interrupted Spot Instances \(p. 477\)](#).

Limitations

- When you hibernate an instance, the data on any instance store volumes is lost.
- You can't hibernate an instance that has more than 150 GB of RAM.
- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to the instance.
- You can't change the instance type or size of an instance when hibernation is enabled.
- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see [Health Checks for Auto Scaling Instances](#) in the *Amazon EC2 Auto Scaling User Guide*.
- You can't hibernate an instance that is configured to boot in UEFI mode.
- If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.
- We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.
- We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.

Configure an existing AMI to support hibernation

The following AMIs support hibernation, but to hibernate an instance that was launched with one of these AMIs, additional configuration is required before you can hibernate the instance.

Additional configuration required for:

- [Amazon Linux 2 released before 2019.08.29 \(p. 646\)](#)
- [Amazon Linux released before 2018.11.16 \(p. 647\)](#)
- [CentOS version 8 or later \(p. 647\)](#)
- [Fedora version 34 or later \(p. 648\)](#)
- [Red Hat Enterprise Linux version 8 or later \(p. 648\)](#)
- [Ubuntu 20.04 LTS - Focal released before serial number 20210820 \(p. 649\)](#)
- [Ubuntu 18.04 - Bionic released before serial number 20190722.1 \(p. 649\)](#)
- [Ubuntu 16.04 - Xenial \(p. 649\)](#)

For more information, see [Update instance software on your Amazon Linux instance \(p. 670\)](#).

No additional configuration is required for the following AMIs because they're already configured to support hibernation:

- Amazon Linux 2 AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- Ubuntu 20.04 LTS - Focal AMI released with serial number 20210820 or later
- Ubuntu 18.04 LTS - Bionic AMI released with serial number 20190722.1 or later

[Amazon Linux 2 released before 2019.08.29](#)

To configure an Amazon Linux 2 AMI released before 2019.08.29 to support hibernation

1. Update the kernel to 4.14.138-114.102 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.14.138-114.102 or later.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see [Create a Linux AMI from an instance \(p. 146\)](#).

Amazon Linux released before 2018.11.16

To configure an Amazon Linux AMI released before 2018.11.16 to support hibernation

1. Update the kernel to 4.14.77-70.59 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.14.77-70.59 or greater.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see [Create a Linux AMI from an instance \(p. 146\)](#).

CentOS version 8 or later

To configure a CentOS version 8 or later AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
```

3. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Fedora version 34 or later

To configure a Fedora version 34 or later AMI to support hibernation

1. Update the kernel to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo dnf install ec2-hibinit-agent
```

3. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

4. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

5. Confirm that the kernel version is updated to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Red Hat Enterprise Linux version 8 or later

To configure a Red Hat Enterprise Linux 8 AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
```

3. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 20.04 LTS - Focal released before serial number 20210820

To configure an Ubuntu 20.04 LTS - Focal AMI released before serial number 20210820 to support hibernation

1. Update the linux-aws-kernel to 5.8.0-1038.40 or later, and grub2 to 2.04-1ubuntu26.13 or later.

```
[ec2-user ~]$ sudo apt update  
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

3. Confirm that the kernel version is updated to 5.8.0-1038.40 or later.

```
[ec2-user ~]$ uname -a
```

4. Confirm that the grub2 version is updated to 2.04-1ubuntu26.13 or later.

```
[ec2-user ~]$ dpkg --list | grep grub2-common
```

Ubuntu 18.04 - Bionic released before serial number 20190722.1

To configure an Ubuntu 18.04 LTS AMI released before serial number 20190722.1 to support hibernation

1. Update the kernel to 4.15.0-1044 or later.

```
[ec2-user ~]$ sudo apt update  
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.15.0-1044 or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 16.04 - Xenial

To configure Ubuntu 16.04 LTS to support hibernation, you need to install the linux-aws-hwe kernel package version 4.15.0-1058-aws or later and the ec2-hibinit-agent.

To configure an Ubuntu 16.04 LTS AMI to support hibernation

1. Update the kernel to 4.15.0-1058-aws or later.

```
[ec2-user ~]$ sudo apt update
[ec2-user ~]$ sudo apt install linux-aws-hwe
```

Note

The `linux-aws-hwe` kernel package is fully supported by Canonical. The package will continue to receive regular updates until standard support for Ubuntu 16.04 LTS ends in April 2021, and will receive additional security updates until the Extended Security Maintenance support ends in 2024. For more information, see [Amazon EC2 Hibernation for Ubuntu 16.04 LTS now available](#) on the Canonical Ubuntu Blog.

2. Install the `ec2-hibernate-agent` package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibernate-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to `4.15.0-1058-aws` or later.

```
[ec2-user ~]$ uname -a
```

Enable hibernation for an instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

Important

You can't enable or disable hibernation for an instance after you launch it.

Console

To enable hibernation using the console

1. Follow the [Launch an instance using the Launch Instance Wizard \(p. 580\)](#) procedure.
2. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI that supports hibernation. For more information about supported AMIs, see [Hibernation prerequisites \(p. 642\)](#).
3. On the **Choose an Instance Type** page, select a supported instance type, and choose **Next: Configure Instance Details**. For information about supported instance types, see [Hibernation prerequisites \(p. 642\)](#).
4. On the **Configure Instance Details** page, for **Stop - Hibernate Behavior**, select the **Enable hibernation as an additional stop behavior** check box.
5. On the **Add Storage** page, for the root volume, specify the following information:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume Type**, select a supported EBS volume type, General Purpose SSD (`gp2` and `gp3`) or Provisioned IOPS SSD (`io1` and `io2`).
 - For **Encryption**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Hibernation prerequisites \(p. 642\)](#).

6. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

AWS CLI

To enable hibernation using the AWS CLI

Use the [run-instances](#) command to launch an instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type m5.large \
  --block-device-mappings file://mapping.json \
  --hibernation-options Configured=true \
  --count 1 \
  --key-name MyKeyPair
```

Specify the following in `mapping.json`.

```
[ \
  { \
    "DeviceName": "/dev/xvda", \
    "Ebs": { \
      "VolumeSize": 30, \
      "VolumeType": "gp2", \
      "Encrypted": true \
    } \
  } \
]
```

Note

The value for `DeviceName` must match the root device name that's associated with the AMI. To find the root device name, use the [describe-images](#) command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit `"Encrypted": true`.

PowerShell

To enable hibernation using the AWS Tools for Windows PowerShell

Use the [New-EC2Instance](#) command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the `-BlockDeviceMappings` parameter. Enable hibernation using the `-HibernationOptions_Configured $true` parameter.

```
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true

PS C:\> New-EC2Instance ` 
        -ImageId ami-0abcdef1234567890 `
```

```
-InstanceType m5.large
-BlockDeviceMappings $ebs_encrypt
-HibernationOptions_Configured $true
-MinCount 1
-MaxCount 1
-KeyName MyKeyPair
```

Note

The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the [Get-EC2Image](#) command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit Encrypted = \$true from the block device mapping.

New console

To view if an instance is enabled for hibernation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **Stop-hibernate behavior**. **Enabled** indicates that the instance is enabled for hibernation.

Old console

To view if an instance is enabled for hibernation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, in the details pane, inspect **Stop - Hibernation behavior**. **Enabled** indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation using the AWS CLI

Use the [describe-instances](#) command and specify the --filters "Name=hibernation-options.configured,Values=true" parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \
--filters "Name=hibernation-options.configured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
    "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the `-Filter @{ Name="hibernation-options.configured"; Value="true"}` parameter to filter instances that are enabled for hibernation.

```
Get-EC2Instance  
-Filter @{ Name="hibernation-options.configured"; Value="true"}
```

The output lists the EC2 instances that are enabled for hibernation.

Disable KASLR on an instance (Ubuntu only)

To run hibernation on a newly launched instance with Ubuntu 16.04 LTS - Xenial, Ubuntu 18.04 LTS - Bionic released with serial number 20190722.1 or later, or Ubuntu 20.04 LTS - Focal released with serial number 20210820 or later, we recommend disabling KASLR (Kernel Address Space Layout Randomization). On Ubuntu 16.04 LTS, Ubuntu 18.04 LTS, or Ubuntu 20.04 LTS, KASLR is enabled by default.

KASLR is a standard Linux kernel security feature that helps to mitigate exposure to and ramifications of yet-undiscovered memory access vulnerabilities by randomizing the base address value of the kernel. With KASLR enabled, there is a possibility that the instance might not resume after it has been hibernated.

To learn more about KASLR, see [Ubuntu Features](#).

To disable KASLR on an instance launched with Ubuntu

1. Connect to your instance using SSH. For more information, see [Connect to your Linux instance using SSH \(p. 614\)](#).
2. Open the `/etc/default/grub.d/50-cloudimg-settings.cfg` file in your editor of choice. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line to append the `nokaslr` option to its end, as shown in the following example.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0 nvme_core.io_timeout=4294967295  
nokaslr"
```

3. Save the file and exit your editor.
4. Run the following command to rebuild the grub configuration.

```
[ec2-user ~]$ sudo update-grub
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Run the following command to confirm that `nokaslr` has been added.

```
[ec2-user ~]$ cat /proc/cmdline
```

The output of the command should include the `nokaslr` option.

Hibernate an instance

You can hibernate an instance if the instance is [enabled for hibernation \(p. 650\)](#) and meets the [hibernation prerequisites \(p. 642\)](#). If an instance cannot hibernate successfully, a normal shutdown occurs.

New console

To hibernate an Amazon EBS-backed instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and choose **Instance state, Hibernate instance**. If **Hibernate instance** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see [Hibernate prerequisites \(p. 642\)](#).
4. When prompted for confirmation, choose **Hibernate**. It can take a few minutes for the instance to hibernate. The instance state first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

Old console

To hibernate an Amazon EBS-backed instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and choose **Actions, Instance State, Stop - Hibernate**. If **Stop - Hibernate** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see [Hibernate prerequisites \(p. 642\)](#).
4. In the confirmation dialog box, choose **Yes, Stop - Hibernate**. It can take a few minutes for the instance to hibernate. The **Instance State** first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

AWS CLI

To hibernate an Amazon EBS-backed instance using the AWS CLI

Use the [stop-instances](#) command and specify the `--hibernate` parameter.

```
aws ec2 stop-instances \
--instance-ids i-1234567890abcdef0 \
--hibernate
```

PowerShell

To hibernate an Amazon EBS-backed instance using the AWS Tools for Windows PowerShell

Use the [Stop-EC2Instance](#) command and specify the `-Hibernate $true` parameter.

```
Stop-EC2Instance ^
-InstanceId i-1234567890abcdef0 ^
-Hibernate $true
```

New console

To view if hibernation was initiated on an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **State transition message**. The message **Client.UserInitiatedHibernate: User initiated hibernate** indicates that hibernation was initiated on the instance.

Old console

To view if hibernation was initiated on an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, in the details pane, inspect **State transition reason message**. The message **Client.UserInitiatedHibernate: User initiated hibernate** indicates that hibernation was initiated on the instance.

AWS CLI

To view if hibernation was initiated on an instance using the AWS CLI

Use the [describe-instances](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \
--filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the instance.

```
"StateReason": {
    "Code": "Client.UserInitiatedHibernate"
}
```

PowerShell

To view if hibernation was initiated on an instance using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance ^
-Filter @{Name="state-reason-code";Value="Client.UserInitiatedHibernate"}
```

The output lists the EC2 instances on which hibernation was initiated.

Start a hibernated instance

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

New console

To start a hibernated instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.

3. Select a hibernated instance, and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the `running` state. During this time, the instance [status checks \(p. 946\)](#) show the instance in a failed state until the instance has started.

Old console

To start a hibernated instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Actions, Instance State, Start**. It can take a few minutes for the instance to enter the `running` state. During this time, the instance [status checks \(p. 946\)](#) show the instance in a failed state until the instance has started.

AWS CLI

To start a hibernated instance using the AWS CLI

Use the [start-instances](#) command.

```
aws ec2 start-instances \
--instance-ids i-1234567890abcdef0
```

PowerShell

To start a hibernated instance using the AWS Tools for Windows PowerShell

Use the [Start-EC2Instance](#) command.

```
Start-EC2Instance ^
-InstanceId i-1234567890abcdef0
```

Troubleshoot hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about two minutes after launch before hibernating.

Takes too long to transition from `stopping` to `stopped`, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the `stopping` state to `stopped`, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

Check the instance system log and look for messages that are related to hibernation. To access the system log, [connect \(p. 611\)](#) to the instance or use the [get-console-output](#) command. Find the log lines from the `hibinit-agent`. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough:
`hibinit-agent: Insufficient disk space. Cannot create setup for hibernation.
Please allocate a larger root device.`

If the last log line from the `hibinit-agent` is `hibinit-agent: Running: swapoff /swap`, hibernation was successfully configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see [Hibernation prerequisites \(p. 642\)](#). If you used your own AMI, make sure that you followed the instructions for [Configure an existing AMI to support hibernation \(p. 646\)](#).

Instance "stuck" in the stopping state

If you hibernated your instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance \(p. 1723\)](#).

Reboot your instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it keeps its public DNS name (IPv4), private and public IPv4 address, IPv6 address (if applicable), and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and starting your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see [Scheduled events for your instances \(p. 952\)](#).

We recommend that you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance instead of running the operating system reboot command from your instance. If you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance, we perform a hard reboot if the instance does not cleanly shut down within a few minutes. If you use AWS CloudTrail, then using Amazon EC2 to reboot your instance also creates an API record of when your instance was rebooted.

New console

To reboot an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance state, Reboot instance**.
4. Choose **Reboot** when prompted for confirmation. The instance remains in the running state.

Old console

To reboot an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance State, Reboot**.
4. Choose **Yes, Reboot** when prompted for confirmation. The instance remains in the running state.

To reboot an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [reboot-instances \(AWS CLI\)](#)
- [Restart-EC2Instance \(AWS Tools for Windows PowerShell\)](#)

To run a controlled fault injection experiment

You can use AWS Fault Injection Simulator to test how your application responds when your instance is rebooted. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS.

- If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.
- If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information about the types of instance events, see [Scheduled events for your instances \(p. 952\)](#).

Contents

- [Identify instances scheduled for retirement \(p. 658\)](#)
- [Actions to take for EBS-backed instances scheduled for retirement \(p. 659\)](#)
- [Actions to take for instance-store backed instances scheduled for retirement \(p. 660\)](#)

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement using the Amazon EC2 console or the command line.

Important

If an instance is scheduled for retirement, we recommend that you take action as soon as possible because the instance might be unreachable. (The email notification you receive states the following: "Due to this degradation your instance could already be unreachable.") For more information about the recommended action you should take, see [Check if your instance is reachable](#).

Ways to identify instances scheduled for retirement

- [Email notification \(p. 659\)](#)

- [Console identification \(p. 659\)](#)

Email notification

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date.

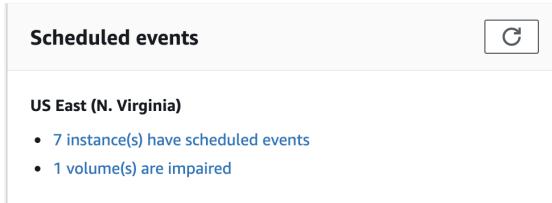

The email is sent to the primary account holder and the operations contact. For more information, see [Adding, changing, or removing alternate contacts](#) in the *AWS Billing and Cost Management User Guide*.

Console identification

If you use an email account that you do not check regularly for instance retirement notifications, you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **EC2 Dashboard**. Under **Scheduled events**, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.

3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.
4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.
5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

To identify instances scheduled for retirement using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [describe-instance-status](#) (AWS CLI)
- [Get-EC2InstanceState](#) (AWS Tools for Windows PowerShell)

Actions to take for EBS-backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

If you are not sure whether your instance is backed by EBS or instance store, see [Determine the root device type of your instance \(p. 1648\)](#).

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either [connecting \(p. 611\)](#) to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see [Stop and start your instance \(p. 637\)](#). Note that data on instance store volumes is lost when you stop and start your instance.
- If your instance is unreachable, you should take immediate action and perform a [stop/start \(p. 637\)](#) to recover your instance.
- Alternatively, if you want to [terminate \(p. 661\)](#) your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

Create a backup of your instance

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see [Create an Amazon EBS-backed Linux AMI \(p. 144\)](#).

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose **Actions, Launch**. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

Actions to take for instance-store backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

Warning

If your instance store-backed instance passes its retirement date, it is terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if the volumes are attached to an EBS-backed instance.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either [connecting \(p. 611\)](#) to or pinging your instance.
- If your instance is unreachable, there is likely very little that can be done to recover your instance. For more information, see [Troubleshoot an unreachable instance \(p. 1747\)](#). AWS will terminate your instance on the scheduled retirement date, so, for an unreachable instance, you can immediately [terminate \(p. 661\)](#) the instance yourself.

Launch a replacement instance

Create an instance store-backed AMI from your instance using the AMI tools, as described in [Create an instance store-backed Linux AMI \(p. 149\)](#). From the Amazon EC2 console, select your new AMI and then choose **Actions, Launch**. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

Convert your instance to an EBS-backed instance

Transfer your data to an EBS volume, take a snapshot of the volume, and then create AMI from the snapshot. You can launch a replacement instance from your new AMI. For more information, see [Convert your instance store-backed AMI to an Amazon EBS-backed AMI \(p. 160\)](#).

Terminate your instance

You can delete your instance when you no longer need it. This is referred to as *terminating* your instance. As soon as the state of an instance changes to **shutting-down** or **terminated**, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop and start your instance, or hibernate it, see [Stop and start your instance \(p. 637\)](#) or [Hibernate your On-Demand Linux instance \(p. 640\)](#). For more information, see [Differences between reboot, stop, hibernate, and terminate \(p. 577\)](#).

Instance termination

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You cannot delete the terminated instance entry yourself. After an instance is terminated, resources such as tags and volumes are gradually disassociated from the instance and may no longer be visible on the terminated instance after a short while.

When an instance terminates, the data on any instance store volumes associated with that instance is deleted.

By default, Amazon EBS root device volumes are automatically deleted when the instance terminates. However, by default, any additional EBS volumes that you attach at launch, or any EBS volumes that you attach to an existing instance persist even after the instance terminates. This behavior is controlled by the volume's `DeleteOnTermination` attribute, which you can modify. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 665\)](#).

You can prevent an instance from being terminated accidentally by someone using the AWS Management Console, the CLI, and the API. This feature is available for both Amazon EC2 instance store-backed and Amazon EBS-backed instances. Each instance has a `DisableApiTermination` attribute with the default value of `false` (the instance can be terminated through Amazon EC2). You can modify this instance attribute while the instance is running or stopped (in the case of Amazon EBS-backed instances). For more information, see [Enable termination protection \(p. 663\)](#).

You can control whether an instance should stop or terminate when shutdown is initiated from the instance using an operating system command for system shutdown. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).

If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

Terminating multiple instances with termination protection across Availability Zones

If you terminate multiple instances across multiple Availability Zones, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

For example, say you have the following instances:

Instance	Availability Zone	Terminate protection
Instance A	us-east-1a	Disabled
Instance B		Disabled
Instance C	us-east-1b	Enabled
Instance D		Disabled

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance A** and **Instance B** are successfully terminated because none of the specified instances in `us-east-1a` are enabled for termination protection.
- **Instance C** and **Instance D** fail to terminate because at least one of the specified instances in `us-east-1b` (**Instance C**) is enabled for termination protection.

What happens when you terminate an instance

When an EC2 instance is terminated using the `terminate-instances` command, the following is registered at the OS level:

- The API request will send a button press event to the guest.
- Various system services will be stopped as a result of the button press event. `systemd` handles a graceful shutdown of the system. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown will be initiated.
- The instance will shut down when the graceful shutdown process exits. There is no configurable OS shutdown time.

Terminate an instance

You can terminate an instance using the AWS Management Console or the command line.

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using the `shutdown` or `poweroff` commands), the instance stops. The `halt` command does not initiate a shutdown. If used, the instance does not terminate; instead, it places the CPU into HALT and the instance remains running.

New console

To terminate an instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. Select the instance, and choose **Instance state, Terminate instance**.
5. Choose **Terminate** when prompted for confirmation.

Old console

To terminate an instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. Select the instance, and choose **Actions, Instance State, Terminate**.
5. Choose **Yes, Terminate** when prompted for confirmation.

To terminate an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [terminate-instances \(AWS CLI\)](#)
- [Stop-EC2Instance \(AWS Tools for Windows PowerShell\)](#)

To run a controlled fault injection experiment

You can use AWS Fault Injection Simulator to test how your application responds when your instance is terminated. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Enable termination protection

By default, you can terminate your instance using the Amazon EC2 console, command line interface, or API. To prevent your instance from being accidentally terminated using Amazon EC2, you can enable *termination protection* for the instance. The `DisableApiTermination` attribute controls whether the

instance can be terminated using the console, CLI, or API. By default, termination protection is disabled for your instance. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped (for Amazon EBS-backed instances).

The `DisableApiTermination` attribute does not prevent you from terminating an instance by initiating shutdown from the instance (using an operating system command for system shutdown) when the `InstanceInitiatedShutdownBehavior` attribute is set. For more information, see [Change the instance initiated shutdown behavior \(p. 665\)](#).

Limitations

You can't enable termination protection for Spot Instances—a Spot Instance is terminated when the Spot price exceeds the amount you're willing to pay for Spot Instances. However, you can prepare your application to handle Spot Instance interruptions. For more information, see [Spot Instance interruptions \(p. 475\)](#).

The `DisableApiTermination` attribute does not prevent Amazon EC2 Auto Scaling from terminating an instance. For instances in an Auto Scaling group, use the following Amazon EC2 Auto Scaling features instead of Amazon EC2 termination protection:

- To prevent instances that are part of an Auto Scaling group from terminating on scale in, use instance scale-in protection. For more information, see [Using instance scale-in protection](#) in the *Amazon EC2 Auto Scaling User Guide*.
- To prevent Amazon EC2 Auto Scaling from terminating unhealthy instances, suspend the `ReplaceUnhealthy` process. For more information, see [Suspending and Resuming Scaling Processes](#) in the *Amazon EC2 Auto Scaling User Guide*.
- To specify which instances Amazon EC2 Auto Scaling should terminate first, choose a termination policy. For more information, see [Customizing the Termination Policy](#) in the *Amazon EC2 Auto Scaling User Guide*.

To enable termination protection for an instance at launch time

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the dashboard, choose **Launch Instance** and follow the directions in the wizard.
3. On the **Configure Instance Details** page, select the **Enable termination protection** check box.

To enable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Enable**.

To disable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Disable**.

To enable or disable termination protection using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Change the instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using a command such as **shutdown** or **poweroff**), the instance stops (Note that **halt** does not issue a **poweroff** command and, if used, the instance will not terminate; instead, it will place the CPU into HLT and the instance will remain running). You can change this behavior using the `InstanceInitiatedShutdownBehavior` attribute for the instance so that it terminates instead. You can update this attribute while the instance is running or stopped.

You can update the `InstanceInitiatedShutdownBehavior` attribute using the Amazon EC2 console or the command line. The `InstanceInitiatedShutdownBehavior` attribute only applies when you perform a shutdown from the operating system of the instance itself; it does not apply when you stop an instance using the `StopInstances` API or the Amazon EC2 console.

To change the shutdown behavior of an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions, Instance settings, Change shutdown behavior**. The current behavior is selected.
5. To change the behavior, select **Stop** or **Terminate** from **Shutdown behavior** and then choose **Apply**.

To change the shutdown behavior of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Preserve Amazon EBS volumes on instance termination

When an instance terminates, Amazon EC2 uses the value of the `DeleteOnTermination` attribute for each attached Amazon EBS volume to determine whether to preserve or delete the volume.

The default value for the `DeleteOnTermination` attribute differs depending on whether the volume is the root volume of the instance or a non-root volume attached to the instance.

Root volume

By default, the `DeleteOnTermination` attribute for the root volume of an instance is set to `true`. Therefore, the default is to delete the root volume of the instance when the instance terminates. The `DeleteOnTermination` attribute can be set by the creator of an AMI as well as by the person who launches an instance. When the attribute is changed by the creator of an AMI or by the person who launches an instance, the new setting overrides the original AMI default setting. We recommend that you verify the default setting for the `DeleteOnTermination` attribute after you launch an instance with an AMI.

Non-root volume

By default, when you [attach a non-root EBS volume to an instance \(p. 1375\)](#), its `DeleteOnTermination` attribute is set to `false`. Therefore, the default is to preserve these volumes. After the instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. You must delete a volume to avoid incurring further charges. For more information, see [Delete an Amazon EBS volume \(p. 1402\)](#).

To verify the value of the `DeleteOnTermination` attribute for an EBS volume that is in use, look at the instance's block device mapping. For more information, see [View the EBS volumes in an instance block device mapping \(p. 1661\)](#).

You can change the value of the `DeleteOnTermination` attribute for a volume when you launch the instance or while the instance is running.

Examples

- [Change the root volume to persist at launch using the console \(p. 666\)](#)
- [Change the root volume to persist at launch using the command line \(p. 666\)](#)
- [Change the root volume of a running instance to persist using the command line \(p. 667\)](#)

Change the root volume to persist at launch using the console

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

To change the root volume of an instance to persist at launch using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console dashboard, select **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose an AMI and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect the **Delete On Termination** check box for the root volume.
6. Complete the remaining wizard pages, and then choose **Launch**.

In the new console experience, you can verify the setting by viewing details for the root device volume on the instance's details pane. On the **Storage** tab, under **Block devices**, scroll right to view the **Delete on termination** setting for the volume. By default, **Delete on termination** is Yes. If you change the default behavior, **Delete on termination** is No.

In the old console experience, you can verify the setting by viewing details for the root device volume on the instance's details pane. Next to **Block devices**, choose the entry for the root device volume. By default, **Delete on termination** is True. If you change the default behavior, **Delete on termination** is False.

Change the root volume to persist at launch using the command line

When you launch an EBS-backed instance, you can use one of the following commands to change the root device volume to persist. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [run-instances \(AWS CLI\)](#)
- [New-EC2Instance \(AWS Tools for Windows PowerShell\)](#)

For example, add the following option to your `run-instances` command:

```
--block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`:

```
[  
 {
```

```
[{"DeviceName": "/dev/sda1",  
 "Ebs": {  
     "DeleteOnTermination": false,  
     "SnapshotId": "snap-1234567890abcdef0",  
     "VolumeType": "gp2"  
   }  
}]
```

Change the root volume of a running instance to persist using the command line

You can use one of the following commands to change the root device volume of a running EBS-backed instance to persist. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 3\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

For example, use the following command:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings  
file://mapping.json
```

Specify the following in `mapping.json`:

```
[  
  {  
    "DeviceName": "/dev/sda1",  
    "Ebs": {  
      "DeleteOnTermination": false  
    }  
  }  
]
```

Troubleshoot instance termination

If you terminate your instance and another instance starts, most likely you have configured automatic scaling through a feature like EC2 Fleet or Amazon EC2 Auto Scaling.

If your instance is in the shutting-down state for longer than usual, it should be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see [Delayed instance termination \(p. 1726\)](#).

Recover your instance

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. Terminated instances cannot be recovered.

A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata. If the impaired instance has a public IPv4 address, the instance retains the public IPv4 address after recovery. If the impaired instance is in a placement group, the recovered instance runs in the placement group.

When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you will be notified by the Amazon SNS topic that you selected when you created the alarm and associated

the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic will receive an email notification that includes the status of the recovery attempt and any further instructions. You will notice an instance reboot on the recovered instance.

Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

Topics

- [Requirements \(p. 668\)](#)
- [Create an Amazon CloudWatch alarm to recover an instance \(p. 668\)](#)
- [Troubleshoot instance recovery failures \(p. 668\)](#)

Requirements

The recover action is supported by an instance if it has the following characteristics:

- The instance uses default or dedicated instance tenancy.
- The instance does not have instance store volumes.
- The instance uses one of the following instance types:
 - General purpose: A1 | M3 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | T1 | T2 | T3 | T3a | T4g
 - Compute optimized: C3 | C4 | C5 | C5a | C5n | C6a | C6g | C6gn | C6i
 - Memory optimized: R3 | R4 | R5 | R5a | R5b | R5n | R6g | R6i | high memory (u-*), virtualized only | X1 | X1e
 - Accelerated computing: G3 | G5g | Inf1 | P2 | P3 | VT1

To view the instance types that support the recover action

Use the following [describe-instance-types](#) command.

```
aws ec2 describe-instance-types --filters Name=auto-recovery-supported,Values=true  
--query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Create an Amazon CloudWatch alarm to recover an instance

For information about creating an Amazon CloudWatch alarm to recover an instance, see [Add recover actions to Amazon CloudWatch alarms \(p. 1004\)](#).

Troubleshoot instance recovery failures

The following issues can cause automatic recovery of your instance to fail:

- Temporary, insufficient capacity of replacement hardware.
- The instance has an attached instance store storage, which is an unsupported configuration for automatic instance recovery.

- There is an ongoing Service Health Dashboard event that prevented the recovery process from successfully executing. Refer to <http://status.aws.amazon.com/> for the latest service availability information.
- The instance has reached the maximum daily allowance of three recovery attempts.

The automatic recovery process attempts to recover your instance for up to three separate failures per day. If the instance system status check failure persists, we recommend that you manually stop and start the instance. For more information, see [Stop and start your instance \(p. 637\)](#).

Your instance may subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

Configure your Amazon Linux instance

After you have successfully launched and logged into your Amazon Linux instance, you can make changes to it. There are many different ways you can configure an instance to meet the needs of a specific application. The following are some common tasks to help get you started.

Contents

- [Common configuration scenarios \(p. 669\)](#)
- [Manage software on your Amazon Linux instance \(p. 670\)](#)

- [Set up dynamic DNS on Your Amazon Linux instance \(p. 718\)](#)
- [Run commands on your Linux instance at launch \(p. 720\)](#)
- [Instance metadata and user data \(p. 726\)](#)

Common configuration scenarios

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code. For more information on installing and building software from these locations, see [Manage software on your Amazon Linux instance \(p. 670\)](#).

Amazon Linux instances come pre-configured with an `ec2-user` account, but you may want to add other user accounts that do not have super-user privileges. For more information on adding and removing user accounts, see [Manage user accounts on your Amazon Linux instance \(p. 675\)](#).

The default time configuration for Amazon Linux instances uses Amazon Time Sync Service to set the system time on an instance. The default time zone is UTC. For more information on setting the time zone for an instance or using your own time server, see [Set the time for your Linux instance \(p. 685\)](#).

If you have your own network with a domain name registered to it, you can change the hostname of an instance to identify itself as part of that domain. You can also change the system prompt to

show a more meaningful name without changing the hostname settings. For more information, see [Change the hostname of your Amazon Linux instance \(p. 715\)](#). You can configure an instance to use a dynamic DNS service provider. For more information, see [Set up dynamic DNS on Your Amazon Linux instance \(p. 718\)](#).

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: cloud-init directives and shell scripts. For more information, see [Run commands on your Linux instance at launch \(p. 720\)](#).

Manage software on your Amazon Linux instance

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. Many more software packages are available in various software repositories, and even more packages are available for you to build from source code.

- [Install software packages on an Amazon Linux instance \(p. 674\)](#)
- [Prepare to compile software on an Amazon Linux instance \(p. 674\)](#)

It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. For more information, see [Update instance software on your Amazon Linux instance \(p. 670\)](#).

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: `amzn2-core` and `amzn2extra-docker`
- Amazon Linux AMI: `amzn-main` and `amzn-updates`

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository. For more information, see [Add repositories on an Amazon Linux instance \(p. 672\)](#). For help finding packages in enabled repositories, see [Find software packages on an Amazon Linux instance \(p. 673\)](#). For information about installing software on an Amazon Linux instance, see [Install software packages on an Amazon Linux instance \(p. 674\)](#).

Not all software is available in software packages stored in repositories; some software must be compiled on an instance from its source code. For more information, see [Prepare to compile software on an Amazon Linux instance \(p. 674\)](#).

Amazon Linux instances manage their software using the yum package manager. The yum package manager can install, remove, and update software, as well as manage all of the dependencies for each package. Debian-based Linux distributions, like Ubuntu, use the `apt-get` command and `dpkg` package manager, so the `yum` examples in the following sections do not work for those distributions.

Update instance software on your Amazon Linux instance

It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. When you first launch and connect to an Amazon Linux instance, you might see a message asking you to update software packages for security purposes. This section shows how to update an entire system, or just a single package.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Important

If you launched an EC2 instance that uses an Amazon Linux 2 AMI into an IPv6-only subnet, you must connect to the instance and run `sudo amazon-linux-https disable`. This lets your AL2 instance connect to the yum repository in S3 over IPv6 using the http patch service.

To update all packages on an Amazon Linux instance

1. (Optional) Start a **screen** session in your shell window. Sometimes you might experience a network interruption that can disconnect the SSH connection to your instance. If this happens during a long software update, it can leave the instance in a recoverable, although confused state. A **screen** session allows you to continue running the update even if your connection is interrupted, and you can reconnect to the session later without problems.

- a. Execute the **screen** command to begin the session.

```
[ec2-user ~]$ screen
```

- b. If your session is disconnected, log back into your instance and list the available screens.

```
[ec2-user ~]$ screen -ls
There is a screen on:
  17793.pts-0.ip-12-34-56-78 (Detached)
  1 Socket in /var/run/screen/S-ec2-user.
```

- c. Reconnect to the screen using the **screen -r** command and the process ID from the previous command.

```
[ec2-user ~]$ screen -r 17793
```

- d. When you are finished using **screen**, use the **exit** command to close the session.

```
[ec2-user ~]$ exit
[screen is terminating]
```

2. Run the **yum update** command. Optionally, you can add the **--security** flag to apply only security updates.

```
[ec2-user ~]$ sudo yum update
```

3. Review the packages listed, enter **y**, and press Enter to accept the updates. Updating all of the packages on a system can take several minutes. The **yum** output shows the status of the update while it is running.
4. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

To update a single package on an Amazon Linux instance

Use this procedure to update a single package (and its dependencies) and not the entire system.

1. Run the **yum update** command with the name of the package to update.

```
[ec2-user ~]$ sudo yum update openssl
```

2. Review the package information listed, enter **y**, and press Enter to accept the update or updates. Sometimes there will be more than one package listed if there are package dependencies that must be resolved. The **yum** output shows the status of the update while it is running.
3. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

Add repositories on an Amazon Linux instance

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: `amzn2-core` and `amzn2extra-docker`
- Amazon Linux AMI: `amzn-main` and `amzn-updates`

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a different repository with **yum**, you need to add the repository information to the `/etc/yum.conf` file or to its own `repository.repo` file in the `/etc/yum.repos.d` directory. You can do this manually, but most yum repositories provide their own `repository.repo` file at their repository URL.

To determine what yum repositories are already installed

- List the installed yum repositories with the following command:

```
[ec2-user ~]$ yum repolist all
```

The resulting output lists the installed repositories and reports the status of each. Enabled repositories display the number of packages they contain.

To add a yum repository to `/etc/yum.repos.d`

1. Find the location of the `.repo` file. This will vary depending on the repository you are adding. In this example, the `.repo` file is at <https://www.example.com/repository.repo>.
2. Add the repository with the **yum-config-manager** command.

```
[ec2-user ~]$ sudo yum-config-manager --add-repo https://www.example.com/repository.repo
Loaded plugins: priorities, update-motd, upgrade-helper
adding repo from: https://www.example.com/repository.repo
grabbing file https://www.example.com/repository.repo to /etc/yum.repos.d/repository.repo
repository.repo                                         | 4.0 kB     00:00
repo saved to /etc/yum.repos.d/repository.repo
```

After you install a repository, you must enable it as described in the next procedure.

To enable a yum repository in /etc/yum.repos.d

- Use the **yum-config-manager** command with the --enable *repository* flag. The following command enables the Extra Packages for Enterprise Linux (EPEL) repository from the Fedora project. By default, this repository is present in /etc/yum.repos.d on Amazon Linux AMI instances, but it is not enabled.

```
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

Note

To enable the EPEL repository on Amazon Linux 2, use the following command:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
```

For information on enabling the EPEL repository on other distributions, such as Red Hat and CentOS, see the EPEL documentation at <https://fedoraproject.org/wiki/EPEL>.

Find software packages on an Amazon Linux instance

You can use the **yum search** command to search the descriptions of packages that are available in your configured repositories. This is especially helpful if you don't know the exact name of the package you want to install. Simply append the keyword search to the command; for multiple word searches, wrap the search query with quotation marks.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

```
[ec2-user ~]$ sudo yum search "find"
```

The following is example output for Amazon Linux 2.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd
=====
N/S matched: find =====
findutils.x86_64 : The GNU versions of find utilities (find and xargs)

Multiple word search queries in quotation marks only return results that match the exact query. If you don't see the expected package, simplify your search to one keyword and then scan the results. You can also try keyword synonyms to broaden your search.

Install software packages on an Amazon Linux instance

The yum package manager is a great tool for installing software, because it can search all of your enabled repositories for different software packages and also handle any dependencies in the software installation process.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a repository

Use the **yum install** *package* command, replacing *package* with the name of the software to install. For example, to install the **links** text-based web browser, enter the following command.

```
[ec2-user ~]$ sudo yum install links
```

To install RPM package files that you have downloaded

You can also use **yum install** to install RPM package files that you have downloaded from the internet. To do this, append the path name of an RPM file to the installation command instead of a repository package name.

```
[ec2-user ~]$ sudo yum install my-package.rpm
```

To list installed packages

To view a list of installed packages on your instance, use the following command.

```
[ec2-user ~]$ yum list installed
```

Prepare to compile software on an Amazon Linux instance

There is a wealth of open-source software available on the internet that has not been pre-compiled and made available for download from a package repository. You might eventually discover a software package that you need to compile yourself, from its source code. For your system to be able to compile software, you need to install several development tools, such as **make**, **gcc**, and **autoconf**.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Because software compilation is not a task that every Amazon EC2 instance requires, these tools are not installed by default, but they are available in a package group called "Development Tools" that is easily added to an instance with the **yum groupinstall** command.

```
[ec2-user ~]$ sudo yum groupinstall "Development Tools"
```

Software source code packages are often available for download (from websites such as <https://github.com/> and <http://sourceforge.net/>) as a compressed archive file, called a tarball. These tarballs will usually have the .tar.gz file extension. You can decompress these archives with the **tar** command.

```
[ec2-user ~]$ tar -xzf software.tar.gz
```

After you have decompressed and unarchived the source code package, you should look for a **README** or **INSTALL** file in the source code directory that can provide you with further instructions for compiling and installing the source code.

To retrieve source code for Amazon Linux packages

Amazon Web Services provides the source code for maintained packages. You can download the source code for any installed packages with the **yumdownloader --source** command.

- Run the **yumdownloader --source package** command to download the source code for *package*. For example, to download the source code for the **htop** package, enter the following command.

```
[ec2-user ~]$ yumdownloader --source htop
Loaded plugins: priorities, update-motd, upgrade-helper
Enabling amzn-updates-source repository
Enabling amzn-main-source repository

(2/2): amzn-main-source/latest/primary_db
| 734 kB  00:00:00
htop-1.0.1-2.3.amzn1.src.rpm
```

The location of the source RPM is in the directory from which you ran the command.

Manage user accounts on your Amazon Linux instance

Each Linux instance launches with a default Linux system user account. The default user name is determined by the AMI that was specified when you launched the instance.

- For Amazon Linux 2 or the Amazon Linux AMI, the user name is **ec2-user**.
- For a CentOS AMI, the user name is **centos** or **ec2-user**.
- For a Debian AMI, the user name is **admin**.

- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- For an Oracle AMI, the user name is `ec2-user`.
- For a Bitnami AMI, the user name is `bitnami`.
- Otherwise, check with the AMI provider.

Note

Linux system users should not be confused with AWS Identity and Access Management (IAM) users. For more information, see [IAM users](#) in the *IAM User Guide*.

Contents

- [Considerations \(p. 676\)](#)
- [Create a user account \(p. 676\)](#)
- [Remove a user account \(p. 678\)](#)

Considerations

Using the default user account is adequate for many applications. However, you may choose to add user accounts so that individuals can have their own files and workspaces. Furthermore, creating user accounts for new users is much more secure than granting multiple (possibly inexperienced) users access to the default user account, because the default user account can cause a lot of damage to a system when used improperly. For more information, see [Tips for Securing Your EC2 Instance](#).

To enable users SSH access to your EC2 instance using a Linux system user account, you must share the SSH key with the user. Alternatively, you can use EC2 Instance Connect to provide access to users without the need to share and manage SSH keys. For more information, see [Connect to your Linux instance using EC2 Instance Connect \(p. 617\)](#).

Create a user account

First create the user account, and then add the SSH public key that allows the user to connect to and log into the instance.

To create a user account

1. [Create a new key pair \(p. 1311\)](#). You must provide the `.pem` file to the user for whom you are creating the user account. They must use this file to connect to the instance.
2. Retrieve the public key from the key pair that you created in the previous step.

```
$ ssh-keygen -y -f /path_to_key_pair/key-pair-name.pem
```

The command returns the public key, as shown in the following example.

```
ssh-rsa
AAAAB3NzaC1yc2EAAAQABAAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706Vhz2ItxCih
+PnDSUaw+WNQn/mZphTk/a/gU8jEzoOWbkM4yxyb/wB96xbxFveSFJuOp/
d6RJhJOI0iBXrlsLnB1ntckij7FbtXJMLvvwJryDUilBMTjYtwB+QhYXUMOzce5Pjz5/i8SeJtjnV3iAoG/

+z7wB3RbBQoQzd8v7yeb70z1PnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
```

3. Connect to the instance.
4. Use the **adduser** command to create the user account and add it to the system (with an entry in the `/etc/passwd` file). The command also creates a group and a home directory for the account. In this example, the user account is named `newuser`.
 - Amazon Linux and Amazon Linux 2

```
[ec2-user ~]$ sudo adduser newuser
```

- Ubuntu

Include the `--disabled-password` parameter to create the user account without a password.

```
[ubuntu ~]$ sudo adduser newuser --disabled-password
```

5. Switch to the new account so that the directory and file that you create will have the proper ownership.

```
[ec2-user ~]$ sudo su - newuser
```

The prompt changes from `ec2-user` to `newuser` to indicate that you have switched the shell session to the new account.

6. Add the SSH public key to the user account. First create a directory in the user's home directory for the SSH key file, then create the key file, and finally paste the public key into the key file, as described in the following sub-steps.
 - a. Create a `.ssh` directory in the `newuser` home directory and change its file permissions to 700 (only the owner can read, write, or open the directory).

```
[newuser ~]$ mkdir .ssh
```

```
[newuser ~]$ chmod 700 .ssh
```

Important

Without these exact file permissions, the user will not be able to log in.

- b. Create a file named `authorized_keys` in the `.ssh` directory and change its file permissions to 600 (only the owner can read or write to the file).

```
[newuser ~]$ touch .ssh/authorized_keys
```

```
[newuser ~]$ chmod 600 .ssh/authorized_keys
```

Important

Without these exact file permissions, the user will not be able to log in.

- c. Open the `authorized_keys` file using your favorite text editor (such as `vim` or `nano`).

```
[newuser ~]$ nano .ssh/authorized_keys
```

Paste the public key that you retrieved in **Step 2** into the file and save the changes.

Important

Ensure that you paste the public key in one continuous line. The public key must not be split over multiple lines.

The user should now be able to log into the **newuser** account on your instance, using the private key that corresponds to the public key that you added to the `authorized_keys` file. For more information about the different methods of connecting to a Linux instance, see [Connect to your Linux instance \(p. 611\)](#).

Remove a user account

If a user account is no longer needed, you can remove that account so that it can no longer be used.

Use the **userdel** command to remove the user account from the system. When you specify the **-r** parameter, the user's home directory and mail spool are deleted. To keep the user's home directory and mail spool, omit the **-r** parameter.

```
[ec2-user ~]$ sudo userdel -r olduser
```

Processor state control for your EC2 instance

C-states control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off).

P-states control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo Boost Technology to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- General purpose: m4.10xlarge | m4.16xlarge | m5.metal | m5d.metal | m5zn.metal | m6i.metal
- Compute optimized: c4.8xlarge | c5.metal | c5n.metal | c6i.metal

AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.

You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However, if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.

The following sections describe the different processor state configurations and how to monitor the effects of your configuration. These procedures were written for, and apply to Amazon Linux; however, they may also work for other Linux distributions with a Linux kernel version of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

Note

The examples on this page use the following:

- The **turbostat** utility to display processor frequency and C-state information. The **turbostat** utility is available on Amazon Linux by default.
- The **stress** command to simulate a workload. To install **stress**, first enable the EPEL repository by running **sudo amazon-linux-extras install epel**, and then run **sudo yum install -y stress**.

If the output does not display the C-state information, include the **--debug** option in the command (**sudo turbostat --debug stress <options>**).

Highest performance with maximum Turbo Boost frequency

This is the default processor state control configuration for the Amazon Linux AMI, and it is recommended for most workloads. This configuration provides the highest performance with lower variability. Allowing inactive cores to enter deeper sleep states provides the thermal headroom required for single or dual core processes to reach their maximum Turbo Boost potential.

The following example shows a c4.8xlarge instance with two cores actively performing work reaching their maximum processor Turbo Boost frequency.

```
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10

In this example, vCPUs 21 and 28 are running at their maximum Turbo Boost frequency because the other cores have entered the C6 sleep state to save power and provide both power and thermal headroom for the working cores. vCPUs 3 and 10 (each sharing a processor core with vCPUs 21 and 28) are in the C1 state, waiting for instruction.

In the following example, all 18 cores are actively performing work, so there is no headroom for maximum Turbo Boost, but they are all running at the "all core Turbo Boost" speed of 3.2 GHz.

```

High performance and low latency by limiting deeper C-states

C-states control the sleep levels that a core may enter when it is inactive. You may want to control C-states to tune your system for latency versus performance. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work. For example, if a core that is assigned to handle network packet interrupts is asleep, there may be a delay in servicing that interrupt. You can configure the system to not use deeper C-states, which reduces the processor reaction latency, but that in turn also reduces the headroom available to other cores for Turbo Boost.

A common scenario for disabling deeper sleep states is a Redis database application, which stores the database in system memory for the fastest possible query response time.

To limit deeper sleep states on Amazon Linux 2

1. Open the /etc/default/grub file with your editor of choice.

```
[ec2-user ~]$ sudo vim /etc/default/grub
```

2. Edit the GRUB_CMDLINE_LINUX_DEFAULT line and add the intel_idle.max_cstate=1 option to set C1 as the deepest C-state for idle cores.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0  
biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1"  
GRUB_TIMEOUT=0
```

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

5. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

To limit deeper sleep states on Amazon Linux AMI

1. Open the /boot/grub/grub.conf file with your editor of choice.

```
[ec2-user ~]$ sudo vim /boot/grub/grub.conf
```

2. Edit the kernel line of the first entry and add the intel_idle.max_cstate=1 option to set C1 as the deepest C-state for idle cores.

```
# created by imagebuilder

```

3. Save the file and exit your editor.
4. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot

The following example shows a c4.8xlarge instance with two cores actively performing work at the "all core Turbo Boost" core frequency.

```

In this example, the cores for vCPUs 19 and 28 are running at 3.2 GHz, and the other cores are in the C1 C-state, awaiting instruction. Although the working cores are not reaching their maximum Turbo Boost frequency, the inactive cores will be much faster to respond to new requests than they would be in the deeper C6 C-state.

Baseline performance with the lowest variability

You can reduce the variability of processor frequency with P-states. P-states control the desired performance (in CPU frequency) from a core. Most workloads perform better in P0, which requests Turbo Boost. But you may want to tune your system for consistent performance rather than bursty performance that can happen when Turbo Boost frequencies are enabled.

Intel Advanced Vector Extensions (AVX or AVX2) workloads can perform well at lower frequencies, and AVX instructions can use more power. Running the processor at a lower frequency, by disabling Turbo Boost, can reduce the amount of power used and keep the speed more consistent. For more information about optimizing your instance configuration and workload for AVX, see <http://www.intel.com/content/dam/www/public/us/en/documents/white-papers/performance-xeon-e5-v3-advanced-vector-extensions-paper.pdf>.

This section describes how to limit deeper sleep states and disable Turbo Boost (by requesting the P1 P-state) to provide low-latency and the lowest processor speed variability for these types of workloads.

To limit deeper sleep states and disable Turbo Boost on Amazon Linux 2

1. Open the /etc/default/grub file with your editor of choice.

```
[ec2-user ~]$ sudo vim /etc/default/grub
```

2. Edit the GRUB_CMDLINE_LINUX_DEFAULT line and add the intel_idle.max_cstate=1 option to set C1 as the deepest C-state for idle cores.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0
biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1"
GRUB_TIMEOUT=0
```

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

```
[ec2-user ~]$ grub2-mkconfig -o /boot/grub2/grub.cfg
```

5. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

6. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

```
[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

7. When your workload is finished, you can re-enable Turbo Boost with the following command.

```
[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

To limit deeper sleep states and disable Turbo Boost on Amazon Linux AMI

1. Open the /boot/grub/grub.conf file with your editor of choice.

```
[ec2-user ~]$ sudo vim /boot/grub/grub.conf
```

2. Edit the kernel line of the first entry and add the intel_idle.max_cstate=1 option to set C1 as the deepest C-state for idle cores.

```

```

3. Save the file and exit your editor.
4. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

5. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

```
[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

6. When your workload is finished, you can re-enable Turbo Boost with the following command.

```
[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

The following example shows a c4.8xlarge instance with two vCPUs actively performing work at the baseline core frequency, with no Turbo Boost.

I/O scheduler

The I/O scheduler is a part of the Linux operating system that sorts and merges I/O requests and determines the order in which they are processed.

I/O schedulers are particularly beneficial for devices such as magnetic hard drives, where seek time can be expensive and where it is optimal to merge co-located requests. I/O schedulers have less of an effect with solid state devices and virtualized environments. This is because for solid state devices, sequential and random access don't differ, and for virtualized environments, the host provides its own layer of scheduling.

This topic discusses the Amazon Linux I/O scheduler. For more information about the I/O scheduler used by other Linux distributions, refer to their respective documentation.

Topics

- [Supported schedulers \(p. 684\)](#)
- [Default scheduler \(p. 684\)](#)
- [Change the scheduler \(p. 685\)](#)

Supported schedulers

Amazon Linux supports the following I/O schedulers:

- `deadline` — The *Deadline* I/O scheduler sorts I/O requests and handles them in the most efficient order. It guarantees a start time for each I/O request. It also gives I/O requests that have been pending for too long a higher priority.
- `cfq` — The *Completely Fair Queueing* (CFQ) I/O scheduler attempts to fairly allocate I/O resources between processes. It sorts and inserts I/O requests into per-process queues.
- `noop` — The *No Operation* (noop) I/O scheduler inserts all I/O requests into a FIFO queue and then merges them into a single request. This scheduler does not do any request sorting.

Default scheduler

No Operation (noop) is the default I/O scheduler for Amazon Linux. This scheduler is used for the following reasons:

- Many instance types use virtualized devices where the underlying host performs scheduling for the instance.
- Solid state devices are used in many instance types where the benefits of an I/O scheduler have less effect.
- It is the least invasive I/O scheduler, and it can be customized if needed.

Change the scheduler

Changing the I/O scheduler can increase or decrease performance based on whether the scheduler results in more or fewer I/O requests being completed in a given time. This is largely dependent on your workload, the generation of the instance type that's being used, and the type of device being accessed. If you change the I/O scheduler being used, we recommend that you use a tool, such as **iostop**, to measure I/O performance and to determine whether the change is beneficial for your use case.

You can view the I/O scheduler for a device using the following command, which uses `nvmeOn1` as an example.

```
$ cat /sys/block/nvmeOn1/queue/scheduler
```

To set the I/O scheduler for the device, use the following command.

```
$ echo cfq/deadline/noop > /sys/block/nvmeOn1/queue/scheduler
```

Set the time for your Linux instance

A consistent and accurate time reference is crucial for many server tasks and processes. Most system logs include a time stamp that you can use to determine when problems occurred and in what order the events took place. If you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time are not set correctly, the date in the signature may not match the date of the request, and AWS rejects the request.

Amazon provides the Amazon Time Sync Service, which is accessible from all EC2 instances, and is also used by other AWS services. This service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate current time readings of the Coordinated Universal Time (UTC) global standard through Network Time Protocol (NTP). The Amazon Time Sync Service automatically smooths any leap seconds that are added to UTC.

The Amazon Time Sync Service is available through NTP at the `169.254.169.123` IPv4 address or the `fd00:ec2::123` IPv6 address for any instance running in a VPC. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#). Your instance does not require access to the internet, and you do not have to configure your security group rules or your network ACL rules to allow access. The latest versions of Amazon Linux 2 and Amazon Linux AMIs synchronize with the Amazon Time Sync Service by default.

Use the following procedures to configure the Amazon Time Sync Service on your instance using the `chrony` client. Alternatively, you can use external NTP sources. For more information about NTP and public time sources, see <http://www.ntp.org/>. An instance needs access to the internet for the external NTP time sources to work.

For Windows instances, see [Set the time for a Windows instance](#).

Configure the time for EC2 instances with IPv4 addresses

This section describes how to set the time for EC2 instances with IPv4 addresses depending on the type of Linux distribution.

Configure the Amazon Time Sync Service on Amazon Linux AMI

Note

On Amazon Linux 2, chrony is already installed and configured to use the Amazon Time Sync Service IP address.

With the Amazon Linux AMI, you must edit the `chrony` configuration file to add a server entry for the Amazon Time Sync Service.

To configure your instance to use the Amazon Time Sync Service

1. Connect to your instance and uninstall the NTP service.

```
[ec2-user ~]$ sudo yum erase 'ntp*'
```

2. Install the `chrony` package.

```
[ec2-user ~]$ sudo yum install chrony
```

3. Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`). Verify that the file includes the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If the line is present, then the Amazon Time Sync Service is already configured and you can go to the next step. If not, add the line after any other `server` or `pool` statements that are already present in the file, and save your changes.

4. Restart the `chrony` daemon (`chronyd`).

```
[ec2-user ~]$ sudo service chronyd restart
```

```
Starting chronyd: [ OK ]
```

Note

On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. Use the `chkconfig` command to configure `chronyd` to start at each system boot.

```
[ec2-user ~]$ sudo chkconfig chronyd on
```

6. Verify that `chrony` is using the 169.254.169.123 IP address to synchronize the time.

```
[ec2-user ~]$ chronyc sources -v
```

```
210 Number of sources = 7
```

```
-- Source mode '^' = server, '=' = peer, '#' = local clock.  
/ .- Source state '*' = current synced, '+' = combined , '-' = not combined,
```

```

Configure the Amazon Time Sync Service on Ubuntu

You must edit the chrony configuration file to add a server entry for the Amazon Time Sync Service.

To configure your instance to use the Amazon Time Sync Service

- Connect to your instance and use apt to install the chrony package.

```
ubuntu:~$ sudo apt install chrony
```

Note

If necessary, update your instance first by running sudo apt update.

- Open the /etc/chrony/chrony.conf file using a text editor (such as vim or nano). Add the following line before any other server or pool statements that are already present in the file, and save your changes:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4

Configure the Amazon Time Sync Service on SUSE Linux

Install chrony from <https://software.opensuse.org/package/chrony>.

Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`). Verify that the file contains the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If this line is not present, add it. Comment out any other server or pool lines. Open yaST and enable the chrony service.

Configure the time for EC2 instances with IPv6 addresses

This section explains how the process described in [Configure the time for EC2 instances with IPv4 addresses \(p. 685\)](#) differs if you are configuring Amazon Time Sync Service for EC2 instances that use an IPv6 address. It doesn't explain the entire Amazon Time Sync Service configuration process. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

Note

We don't recommend using both the IPv4 address and the IPv6 address entries together in your `chrony.conf` file. The IPv4 and IPv6 NTP packets come from the same local server for your instance. You will likely get mixed results with some packets coming from the IPv4 endpoint and some from the IPv6 endpoint if you are using both at the same time.

Depending on the Linux distribution you are using, when you reach the step to edit the `chrony.conf` file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (`fd00:ec2::123`) rather than the IPv4 endpoint (`169.254.169.123`):

```
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that `chrony` is using the `fd00:ec2::123` IPv6 address to synchronize time:

```
[ec2-user ~]$ chronyc sources -v
```

In the output, if you see the `fd00:ec2::123` IPv6 address, the configuration is complete.

Change the time zone on Amazon Linux

Amazon Linux instances are set to the UTC (Coordinated Universal Time) time zone by default. You can change the time on an instance to the local time or to another time zone in your network.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To change the time zone on an Amazon Linux 2 instance

1. View the system's current time zone setting.

```
[ec2-user ~]$ timedatectl
```

2. List the available time zones.

```
[ec2-user ~]$ timedatectl list-timezones
```

3. Set the chosen time zone.

```
[ec2-user ~]$ sudo timedatectl set-timezone America/Vancouver
```

To change the time zone on an Amazon Linux instance

1. Identify the time zone to use on the instance. The `/usr/share/zoneinfo` directory contains a hierarchy of time zone data files. Browse the directory structure at that location to find a file for your time zone.

```
[ec2-user ~]$ ls /usr/share/zoneinfo
Africa      Chile     GB          Indian       Mideast    posixrules  US
America    CST6CDT  GB-Eire    Iran        MST        PRC        UTC
Antarctica Cuba      GMT        iso3166.tab MST7MDT   PST8PDT   WET
Arctic      EET       GMTO      Israel      Navajo    right      W-SU
...
```

Some of the entries at this location are directories (such as `America`), and these directories contain time zone files for specific cities. Find your city (or a city in your time zone) to use for the instance.

2. Update the `/etc/sysconfig/clock` file with the new time zone. In this example, we use the time zone data file for Los Angeles, `/usr/share/zoneinfo/America/Los_Angeles`.
 - a. Open the `/etc/sysconfig/clock` file with your favorite text editor (such as `vim` or `nano`). You need to use `sudo` with your editor command because `/etc/sysconfig/clock` is owned by `root`.

```
[ec2-user ~]$ sudo nano /etc/sysconfig/clock
```

- b. Locate the `ZONE` entry, and change it to the time zone file (omitting the `/usr/share/zoneinfo` section of the path). For example, to change to the Los Angeles time zone, change the `ZONE` entry to the following:

```
ZONE="America/Los_Angeles"
```

Note

Do not change the `UTC=true` entry to another value. This entry is for the hardware clock, and does not need to be adjusted when you're setting a different time zone on your instance.

- c. Save the file and exit the text editor.
3. Create a symbolic link between `/etc/localtime` and the time zone file so that the instance finds the time zone file when it references local time information.

```
[ec2-user ~]$ sudo ln -sf /usr/share/zoneinfo/America/Los_Angeles /etc/localtime
```

4. Reboot the system to pick up the new time zone information in all services and applications.

```
[ec2-user ~]$ sudo reboot
```

5. (Optional) Confirm that the current time zone is updated to the new time zone by using the `date` command. The current time zone appears in the output. In the following example, the current time zone is PDT, which refers to the Los Angeles time zone.

```
[ec2-user ~]$ date
Sun Aug 16 05:45:16 PDT 2020
```

Compare timestamps

If you're using the Amazon Time Sync Service, you can compare the timestamps on your Amazon EC2 instances with ClockBound to determine the true time of an event. ClockBound measures the clock accuracy of your EC2 instance, and allows you to check if a given timestamp is in the past or future with respect to your instance's current clock. This information is valuable for determining the order and consistency of events and transactions across EC2 instances, independent of each instance's geographic location.

ClockBound is an open source daemon and library. To learn more about ClockBound, including installation instructions, see [ClockBound on GitHub](#).

Optimize CPU options

Amazon EC2 instances support multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an `m5.xlarge` instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a thread of a CPU core, except for T2 instances and instances powered by AWS Graviton2 processors.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores:** You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core:** You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with default CPU options.

Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

- CPU options can only be specified during instance launch and cannot be modified after launch.
- When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see [Specify CPU options for your instance \(p. 712\)](#).
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see [CPU cores and threads per CPU core per instance type \(p. 692\)](#).
- To disable multithreading, specify one thread per core.

- When you [change the instance type \(p. 382\)](#) of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
- The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.

Specify CPU options for your instance

You can specify CPU options during instance launch.

The following examples describe how to specify the CPU options when using the launch instance wizard and the [run-instances](#) AWS CLI command. You can also use a [launch template \(p. 594\)](#) to specify the CPU options. However, if you use the Amazon EC2 console, the launch template screen currently does not provide a field for specifying the CPU options, but you can specify the CPU options by using the [create-launch-template](#) AWS CLI command. For EC2 Fleet or Spot Fleet, you must specify the CPU options in a launch template.

The following examples are for an `r4.4xlarge` instance type, which has the following [default values \(p. 704\)](#):

- Default CPU cores: 8
- Default threads per core: 2
- Default vCPUs: 16 ($8 * 2$)
- Valid number of CPU cores: 1, 2, 3, 4, 5, 6, 7, 8
- Valid number of threads per core: 1, 2

Disable multithreading

To disable multithreading, specify one thread per core.

To disable multithreading during instance launch (console)

1. Follow the [Launch an instance using the Launch Instance Wizard \(p. 580\)](#) procedure.
2. On the **Configure Instance Details** page, for **CPU options**, choose **Specify CPU options**.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an `r4.4xlarge` instance, choose **8**.
4. To disable multithreading, for **Threads per core**, choose **1**.
5. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

To disable multithreading during instance launch (AWS CLI)

Use the `run-instances` AWS CLI command and specify a value of `1` for `ThreadsPerCore` for the `--cpu-options` parameter. For `CoreCount`, specify the number of CPU cores. In this example, to specify the default CPU core count for an `r4.4xlarge` instance, specify a value of `8`.

```
aws ec2 run-instances \
  --image-id ami-1a2b3c4d \
  --instance-type r4.4xlarge \
  --cpu-options "CoreCount=8,ThreadsPerCore=1" \
  --key-name MyKeyPair
```

Specify a custom number of vCPUs

You can customize the number of CPU cores and threads per core for the instance.

To specify a custom number of vCPUs during instance launch (console)

The following example launches an `r4.4xlarge` instance with six vCPUs.

1. Follow the [Launch an instance using the Launch Instance Wizard \(p. 580\)](#) procedure.
2. On the **Configure Instance Details** page, for **CPU options**, choose **Specify CPU options**.
3. To get six vCPUs, specify three CPU cores and two threads per core, as follows:
 - For **Core count**, choose **3**.
 - For **Threads per core**, choose **2**.
4. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#).

To specify a custom number of vCPUs during instance launch (AWS CLI)

The following example launches an `r4.4xlarge` instance with six vCPUs.

Use the `run-instances` AWS CLI command and specify the number of CPU cores and number of threads in the `--cpu-options` parameter. You can specify three CPU cores and two threads per core to get six vCPUs.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type r4.4xlarge \
--cpu-options "CoreCount=3,ThreadsPerCore=2" \
--key-name MyKeyPair
```

Alternatively, specify six CPU cores and one thread per core (disable multithreading) to get six vCPUs:

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type r4.4xlarge \
--cpu-options "CoreCount=6,ThreadsPerCore=1" \
--key-name MyKeyPair
```

View the CPU options for your instance

You can view the CPU options for an existing instance in the Amazon EC2 console or by describing the instance using the AWS CLI.

New console

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances** and select the instance.
3. On the **Details** tab, under **Host and placement group**, find **Number of vCPUs**.
4. To view core count and threads per core, choose the value for **Number of vCPUs**.

Old console

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances** and select the instance.
3. Choose **Description** and find **Number of vCPUs**.
4. To view core count and threads per core, choose the value for **Number of vCPUs**.

To view the CPU options for an instance (AWS CLI)

Use the `describe-instances` command.

```
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

```
...
    "Instances": [
        {
            "Monitoring": {
```

```
        "State": "disabled"
    },
    "PublicDnsName": "ec2-198-51-100-5.eu-central-1.compute.amazonaws.com",
    "State": {
        "Code": 16,
        "Name": "running"
    },
    "EbsOptimized": false,
    "LaunchTime": "2018-05-08T13:40:33.000Z",
    "PublicIpAddress": "198.51.100.5",
    "PrivateIpAddress": "172.31.2.206",
    "ProductCodes": [],
    "VpcId": "vpc-1a2b3c4d",
    "CpuOptions": {
        "CoreCount": 34,
        "ThreadsPerCore": 1
    },
    "StateTransitionReason": "",
    ...
}
]
...
}
```

In the output that's returned, the `CoreCount` field indicates the number of cores for the instance. The `ThreadsPerCore` field indicates the number of threads per core.

Alternatively, connect to your instance and use a tool such as `lscpu` to view the CPU information for your instance.

You can use AWS Config to record, assess, audit, and evaluate configuration changes for instances, including terminated instances. For more information, see [Getting Started with AWS Config](#) in the [AWS Config Developer Guide](#).

Change the hostname of your Amazon Linux instance

When you launch an instance, it is assigned a hostname. For more information about EC2 hostnames, see [Amazon EC2 instance hostname types \(p. 1053\)](#).

A typical Amazon EC2 private DNS name for an EC2 instance configured to use IP-based naming with an IPv4 address looks something like this: `ip-12-34-56-78.us-west-2.compute.internal`, where the name consists of the internal domain, the service (in this case, `compute`), the region, and a form of the private IPv4 address. Part of this hostname is displayed at the shell prompt when you log into your instance (for example, `ip-12-34-56-78`). Each time you stop and restart your Amazon EC2 instance (unless you are using an Elastic IP address), the public IPv4 address changes, and so does your public DNS name, system hostname, and shell prompt.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Change the system hostname

If you have a public DNS name registered for the IP address of your instance (such as `webserver.mydomain.com`), you can set the system hostname so your instance identifies itself as a part of that domain. This also changes the shell prompt so that it displays the first portion of this name instead of the hostname supplied by AWS (for example, `ip-12-34-56-78`). If you do not have a public DNS name registered, you can still change the hostname, but the process is a little different.

In order for your hostname update to persist, you must verify that the `preserve_hostname` cloud-init setting is set to `true`. You can run the following command to edit or add this setting:

```
sudo vi /etc/cloud/cloud.cfg
```

If the `preserve_hostname` setting is not listed, add the following line of text to the end of the file:

```
preserve_hostname: true
```

To change the system hostname to a public DNS name

Follow this procedure if you already have a public DNS name registered.

1. • For Amazon Linux 2: Use the `hostnamectl` command to set your hostname to reflect the fully qualified domain name (such as `webserver.mydomain.com`).

```
[ec2-user ~]$ sudo hostnamectl set-hostname webserver.mydomain.com
```

- For Amazon Linux AMI: On your instance, open the `/etc/sysconfig/network` configuration file in your favorite text editor and change the `HOSTNAME` entry to reflect the fully qualified domain name (such as `webserver.mydomain.com`).

```
HOSTNAME=webserver.mydomain.com
```

2. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

Alternatively, you can reboot using the Amazon EC2 console (on the **Instances** page, select the instance and choose **Instance state, Reboot instance**).

3. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the `hostname` command should show the fully-qualified domain name.

```
[ec2-user@webserver ~]$ hostname  
webserver.mydomain.com
```

To change the system hostname without a public DNS name

1. • For Amazon Linux 2: Use the `hostnamectl` command to set your hostname to reflect the desired system hostname (such as `webserver`).

```
[ec2-user ~]$ sudo hostnamectl set-hostname webserver.localdomain
```

- For Amazon Linux AMI: On your instance, open the `/etc/sysconfig/network` configuration file in your favorite text editor and change the `HOSTNAME` entry to reflect the desired system hostname (such as `webserver`).

```
HOSTNAME=webserver.localdomain
```

2. Open the `/etc/hosts` file in your favorite text editor and change the entry beginning with `127.0.0.1` to match the example below, substituting your own hostname.

```
127.0.0.1 webserver.localdomain webserver localhost4 localhost4.localdomain4
```

3. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

Alternatively, you can reboot using the Amazon EC2 console (on the **Instances** page, select the instance and choose **Instance state, Reboot instance**).

4. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the **hostname** command should show the fully-qualified domain name.

```
[ec2-user@webserver ~]$ hostname  
webserver.localdomain
```

Change the shell prompt without affecting the hostname

If you do not want to modify the hostname for your instance, but you would like to have a more useful system name (such as **webserver**) displayed than the private name supplied by AWS (for example, `ip-12-34-56-78`), you can edit the shell prompt configuration files to display your system nickname instead of the hostname.

To change the shell prompt to a host nickname

1. Create a file in `/etc/profile.d` that sets the environment variable called **NICKNAME** to the value you want in the shell prompt. For example, to set the system nickname to **webserver**, run the following command.

```
[ec2-user ~]$ sudo sh -c 'echo "export NICKNAME=webserver" > /etc/profile.d/prompt.sh'
```

2. Open the `/etc/bashrc` (Red Hat) or `/etc/bash.bashrc` (Debian/Ubuntu) file in your favorite text editor (such as **vim** or **nano**). You need to use **sudo** with the editor command because `/etc/bashrc` and `/etc/bash.bashrc` are owned by `root`.
3. Edit the file and change the shell prompt variable (`PS1`) to display your nickname instead of the hostname. Find the following line that sets the shell prompt in `/etc/bashrc` or `/etc/bash.bashrc` (several surrounding lines are shown below for context; look for the line that starts with `["$PS1":`):

```
# Turn on checkwinsize
shopt -s checkwinsize
[ "$PS1" = "\s-\v\\\$ " ] && PS1="[\u@\h \w]\\$\ "
# You might want to have e.g. tty in prompt (e.g. more virtual machines)
# and console windows
```

Change the `\h` (the symbol for hostname) in that line to the value of the **NICKNAME** variable.

```
# Turn on checkwinsize
shopt -s checkwinsize
[ "$PS1" = "\s-\v\\\$ " ] && PS1="[\u@\$NICKNAME \w]\\$\ "
# You might want to have e.g. tty in prompt (e.g. more virtual machines)
# and console windows
```

4. (Optional) To set the title on shell windows to the new nickname, complete the following steps.
 - a. Create a file named `/etc/sysconfig/bash-prompt-xterm`.

```
[ec2-user ~]$ sudo touch /etc/sysconfig/bash-prompt-xterm
```

- b. Make the file executable using the following command.

```
[ec2-user ~]$ sudo chmod +x /etc/sysconfig/bash-prompt-xterm
```

- c. Open the /etc/sysconfig/bash-prompt-xterm file in your favorite text editor (such as **vim** or **nano**). You need to use **sudo** with the editor command because /etc/sysconfig/bash-prompt-xterm is owned by root.
- d. Add the following line to the file.

```
echo -ne "\033]0;${USER}@${NICKNAME}: ${PWD/#$HOME/~}\007"
```

5. Log out and then log back in to pick up the new nickname value.

Change the hostname on other Linux distributions

The procedures on this page are intended for use with Amazon Linux only. For more information about other Linux distributions, see their specific documentation and the following articles:

- [How do I assign a static hostname to a private Amazon EC2 instance running RHEL 7 or Centos 7?](#)

Set up dynamic DNS on Your Amazon Linux instance

When you launch an EC2 instance, it is assigned a public IP address and a public DNS (Domain Name System) name that you can use to reach it from the internet. Because there are so many hosts in the Amazon Web Services domain, these public names must be quite long for each name to remain unique. A typical Amazon EC2 public DNS name looks something like this: ec2-12-34-56-78.us-west-2.compute.amazonaws.com, where the name consists of the Amazon Web Services domain, the service (in this case, compute), the region, and a form of the public IP address.

Dynamic DNS services provide custom DNS host names within their domain area that can be easy to remember and that can also be more relevant to your host's use case; some of these services are also free of charge. You can use a dynamic DNS provider with Amazon EC2 and configure the instance to update the IP address associated with a public DNS name each time the instance starts. There are many different providers to choose from, and the specific details of choosing a provider and registering a name with them are outside the scope of this guide.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To use dynamic DNS with Amazon EC2

1. Sign up with a dynamic DNS service provider and register a public DNS name with their service. This procedure uses the free service from [noip.com/free](#) as an example.
2. Configure the dynamic DNS update client. After you have a dynamic DNS service provider and a public DNS name registered with their service, point the DNS name to the IP address for your instance. Many providers (including [noip.com](#)) allow you to do this manually from your account page on their website, but many also support software update clients. If an update client is running on your EC2 instance, your dynamic DNS record is updated each time the IP address changes, as after a shutdown and restart. In this example, you install the noip2 client, which works with the service provided by [noip.com](#).
 - a. Enable the Extra Packages for Enterprise Linux (EPEL) repository to gain access to the noip2 client.

Note

Amazon Linux instances have the GPG keys and repository information for the EPEL repository installed by default; however, Red Hat and CentOS instances must first install the `epel-release` package before you can enable the EPEL repository. For more information and to download the latest version of this package, see <https://fedoraproject.org/wiki/EPEL>.

- For Amazon Linux 2:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
```

- For Amazon Linux AMI:

```
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

- Install the `noip` package.

```
[ec2-user ~]$ sudo yum install -y noip
```

- Create the configuration file. Enter the login and password information when prompted and answer the subsequent questions to configure the client.

```
[ec2-user ~]$ sudo noip2 -C
```

3. Enable the `noip` service.

- For Amazon Linux 2:

```
[ec2-user ~]$ sudo systemctl enable noip.service
```

- For Amazon Linux AMI:

```
[ec2-user ~]$ sudo chkconfig noip on
```

4. Start the `noip` service.

- For Amazon Linux 2:

```
[ec2-user ~]$ sudo systemctl start noip.service
```

- For Amazon Linux AMI:

```
[ec2-user ~]$ sudo service noip start
```

This command starts the client, which reads the configuration file (`/etc/no-ip2.conf`) that you created earlier and updates the IP address for the public DNS name that you chose.

5. Verify that the update client has set the correct IP address for your dynamic DNS name. Allow a few minutes for the DNS records to update, and then try to connect to your instance using SSH with the public DNS name that you configured in this procedure.

Run commands on your Linux instance at launch

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common automated configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch wizard as plain text, as a file (this is useful for launching instances using the command line tools), or as base64-encoded text (for API calls).

If you are interested in more complex automation scenarios, consider using AWS CloudFormation and AWS OpsWorks. For more information, see the [AWS CloudFormation User Guide](#) and the [AWS OpsWorks User Guide](#).

For information about running commands on your Windows instance at launch, see [Run commands on your Windows instance at launch](#) and [Manage Windows instance configuration](#) in the *Amazon EC2 User Guide for Windows Instances*.

In the following examples, the commands from the [Install a LAMP Web Server on Amazon Linux 2 \(p. 25\)](#) are converted to a shell script and a set of cloud-init directives that run when the instance launches. In each example, the following tasks are performed by the user data:

- The distribution software packages are updated.
- The necessary web server, `php`, and `mariadb` packages are installed.
- The `httpd` service is started and turned on via `systemctl`.
- The `ec2-user` is added to the `apache` group.
- The appropriate ownership and file permissions are set for the web directory and the files contained within it.
- A simple web page is created to test the web server and PHP engine.

- [User data and the console \(p. 721\)](#)
- [User data and cloud-init directives \(p. 723\)](#)
- [User data and the AWS CLI \(p. 724\)](#)

Prerequisites

The following examples assume that your instance has a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance \(p. 10\)](#). You must also configure your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Set up to use Amazon EC2 \(p. 5\)](#).

Also, these instructions are intended for use with Amazon Linux 2, and the commands and directives may not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see their specific documentation.

User data and shell scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch. Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

Important

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see [How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance?](#) in the AWS Knowledge Center.

User data shell scripts must start with the `#!` characters and the path to the interpreter you want to read the script (commonly `/bin/bash`). For a great introduction on shell scripting, see [the BASH Programming HOW-TO](#) at the Linux Documentation Project (tldp.org).

Scripts entered as user data are run as the `root` user, so do not use the `sudo` command in the script. Remember that any files you create will be owned by `root`; if you need non-root users to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as `yum update` without the `-y` flag).

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to issue the API call. For more information, see [Using instance profiles](#) in the IAM User Guide. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see [IAM roles for Amazon EC2](#).

The cloud-init output log file (`/var/log/cloud-init-output.log`) captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended.

When a user data script is processed, it is copied to and run from `/var/lib/cloud/instances/instance-id/`. The script is not deleted after it is run. Be sure to delete the user data scripts from `/var/lib/cloud/instances/instance-id/` before you create an AMI from the instance. Otherwise, the script will exist in this directory on any instance launched from the AMI.

User data and the console

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

Specify instance user data at launch

Follow the procedure for launching an instance at [Launch an instance using the Launch Instance Wizard \(p. 580\)](#), but when you get to [the section called "Step 3: Configure Instance Details" \(p. 582\)](#) in that procedure, copy your shell script in the **User data** field, and then complete the launch procedure.

In the example script below, the script creates and configures our web server.

```
#!/bin/bash
yum update -y
amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
yum install -y httpd mariadb-server
systemctl start httpd
systemctl enable httpd
usermod -a -G apache ec2-user
chown -R ec2-user:apache /var/www
chmod 2775 /var/www
find /var/www -type d -exec chmod 2775 {} \;
find /var/www -type f -exec chmod 0664 {} \;
echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

Allow enough time for the instance to launch and run the commands in your script, and then check to see that your script has completed the tasks that you intended.

For our example, in a web browser, enter the URL of the PHP test file the script created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see [Add rules to a security group \(p. 1333\)](#).

(Optional) If your script did not accomplish the tasks you were expecting it to, or if you just want to verify that your script completed without errors, examine the cloud-init output log file at `/var/log/cloud-init-output.log` and look for error messages in the output.

For additional debugging information, you can create a Mime multipart archive that includes a cloud-init data section with the following directive:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends command output from your script to `/var/log/cloud-init-output.log`. For more information about cloud-init data formats and creating Mime multi part archive, see [cloud-init Formats](#).

View and update the instance user data

To update the instance user data, you must first stop the instance. If the instance is running, you can view the user data but you cannot modify it.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

New console

To modify instance user data

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state, Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance settings, Edit user data**.
6. Modify the user data as needed, and then choose **Save**.
7. Restart the instance. The new user data is visible on your instance after you restart it; however, user data scripts are not run.

Old console

To modify instance user data

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance State, Stop**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.

4. When prompted for confirmation, choose **Yes, Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance Settings, View/Change User Data**.
6. In the **View/Change User Data** dialog box, update the user data, and then choose **Save**.
7. Restart the instance. The new user data is visible on your instance after you restart it; however, user data scripts are not run.

User data and cloud-init directives

The cloud-init package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the `.ssh/authorized_keys` file for the `ec2-user` so you can log in with your own private key. For more information, see [cloud-init \(p. 217\)](#).

The cloud-init user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about cloud-init, go to <http://cloudinit.readthedocs.org/en/latest/index.html>.

Important

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see [How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance?](#) in the AWS Knowledge Center.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.

To pass cloud-init directives to an instance with user data

1. Follow the procedure for launching an instance at [Launch an instance using the Launch Instance Wizard \(p. 580\)](#), but when you get to the section called "Step 3: Configure Instance Details" (p. 582) in that procedure, enter your cloud-init directive text in the **User data** field, and then complete the launch procedure.

In the example below, the directives create and configure a web server on Amazon Linux 2. The `#cloud-config` line at the top is required in order to identify the commands as cloud-init directives.

```
#cloud-config
repo_update: true
repo_upgrade: all

packages:
- httpd
- mariadb-server

runcmd:
- [ sh, -c, "amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2" ]
- systemctl start httpd
- sudo systemctl enable httpd
- [ sh, -c, "usermod -a -G apache ec2-user" ]
- [ sh, -c, "chown -R ec2-user:apache /var/www" ]
- chmod 2775 /var/www
- [ find, /var/www, -type, d, -exec, chmod, 2775, {}, \; ]
- [ find, /var/www, -type, f, -exec, chmod, 0664, {}, \; ]
- [ sh, -c, 'echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php' ]
```

2. Allow enough time for the instance to launch and run the directives in your user data, and then check to see that your directives have completed the tasks you intended.

For our example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see [Add rules to a security group \(p. 1333\)](#).

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, examine the output log file at /var/log/cloud-init-output.log and look for error messages in the output. For additional debugging information, you can add the following line to your directives:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends **runcmd** output to /var/log/cloud-init-output.log.

User data and the AWS CLI

You can use the AWS CLI to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see [Retrieve instance user data \(p. 742\)](#).

On Windows, you can use the AWS Tools for Windows PowerShell instead of using the AWS CLI. For more information, see [User data and the Tools for Windows PowerShell](#) in the *Amazon EC2 User Guide for Windows Instances*.

Example: Specify user data at launch

To specify user data when you launch your instance, use the **run-instances** command with the --user-data parameter. With **run-instances**, the AWS CLI performs base64 encoding of the user data for you.

The following example shows how to specify a script as a string on the command line:

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium \
--key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 \
--user-data echo user data
```

The following example shows how to specify a script using a text file. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium \
--key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 \
--user-data file://my_script.txt
```

The following is an example text file with a shell script.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Example: Modify the user data of a stopped instance

You can modify the user data of a stopped instance using the [modify-instance-attribute](#) command. With **modify-instance-attribute**, the AWS CLI does not perform base64 encoding of the user data for you.

- On a **Linux** computer, use the base64 command to encode the user data.

```
base64 my_script.txt >my_script_base64.txt
```

- On a **Windows** computer, use the certutil command to encode the user data. Before you can use this file with the AWS CLI, you must remove the first (BEGIN CERTIFICATE) and last (END CERTIFICATE) lines.

```
certutil -encode my_script.txt my_script_base64.txt  
notepad my_script_base64.txt
```

Use the **--attribute** and **--value** parameters to use the encoded text file to specify the user data. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --  
value file:///my_script_base64.txt
```

Example: Clear the user data of a stopped instance

To delete the existing user data, use the [modify-instance-attribute](#) command as follows:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --user-data Value=
```

Example: View user data

To retrieve the user data for an instance, use the [describe-instance-attribute](#) command. With **describe-instance-attribute**, the AWS CLI does not perform base64 decoding of the user data for you.

```
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData
```

The following is example output with the user data base64 encoded.

```
{  
    "UserData": {  
        "Value":  
        "IyEvYmluL2Jhc2gKeXVtIHVwZGF0ZSAteOpzZXJ2aWNlIGH0dHBkIHN0YXJ0CmNoa2NvbmZpZyBodHRwZCBvbg=="  
    },  
    "InstanceId": "i-1234567890abcdef0"  
}
```

- On a **Linux** computer , use the **--query** option to get the encoded user data and the **base64** command to decode it.

```
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute  
userData --output text --query "UserData.Value" | base64 --decode
```

- On a **Windows** computer, use the **--query** option to get the coded user data and the **certutil** command to decode it. Note that the encoded output is stored in a file and the decoded output is stored in another file.

```
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute
  userData --output text --query "UserData.Value" >my_output.txt
certutil -decode my_output.txt my_output_decoded.txt
type my_output_decoded.txt
```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Instance metadata and user data

Instance metadata is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into [categories \(p. 744\)](#), for example, host name, events, and security groups.

You can also use instance metadata to access *user data* that you specified when launching your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from the Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with the unique bucket name provided to your code in the user data. If you launch more than one instance at the same time, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique `ami-launch-index` number, allowing you to write code that controls what to do. For example, the first host might elect itself as the original node in a cluster. For a detailed AMI launch example, see [Example: AMI launch index value \(p. 752\)](#).

EC2 instances can also include *dynamic data*, such as an instance identity document that is generated when the instance is launched. For more information, see [Dynamic data categories \(p. 752\)](#).

Important

Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance, can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

Use IMDSv2

You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

By default, you can use either IMDSv1 or IMDSv2, or both. The instance metadata service distinguishes between IMDSv1 and IMDSv2 requests based on whether, for any given request, either the `PUT` or `GET` headers, which are unique to IMDSv2, are present in that request. For more information, see [Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service](#).

You can configure the instance metadata service on each instance such that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For more information, see [Configure the instance metadata options \(p. 730\)](#).

To retrieve instance metadata, see [Retrieve instance metadata \(p. 734\)](#).

Note

The examples in this section use the IPv4 address of the instance metadata service: `169.254.169.254`. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: `fd00:ec2::254`. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.

The following example uses a Linux shell script and IMDSv2 to retrieve the top-level instance metadata items. The example:

- Creates a session token lasting six hours (21,600 seconds) using the `PUT` request
- Stores the session token header in a variable named `TOKEN`
- Requests the top-level metadata items using the token

You can run two separate commands, or combine them.

Separate commands

First, generate a token using the following command.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" `
```

Then, use the token to generate top-level metadata items using the following command.

```
[ec2-user ~]$ curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/
```

Combined commands

You can store the token and combine the commands. The following example combines the above two commands and stores the session token header in a variable named TOKEN.

Note

If there is an error in creating the token, instead of a valid token, an error message is stored in the variable, and the command will not work.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in \$TOKEN in the previous example is reused.

```
[ec2-user ~]$ curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/ami-id
```

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a `PUT` request to initiate a session to the instance metadata service. The `PUT` request returns a token that must be included in subsequent `GET` requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all `GET` requests to the instance metadata service. When token usage is set to `required`, requests without a valid token or with an expired token receive a `401 – Unauthorized` HTTP error code. For information about changing the token usage requirement, see [modify-instance-metadata-options](#) in the *AWS CLI Command Reference*.
 - The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.
 - The `PUT` request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.
 - After a token expires, to continue accessing instance metadata, you must create a new session using another `PUT`.
 - You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the instance metadata service. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a `PUT` request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal instance metadata service connection and throttling limits. For more information, see [Query throttling \(p. 741\)](#).

HTTP `GET` and `HEAD` methods are allowed in IMDSv2 instance metadata requests. `PUT` requests are rejected if they contain an `X-Forwarded-For` header.

By default, the response to `PUT` requests has a response hop limit (time to live) of 1 at the IP protocol level. You can adjust the hop limit using the `modify-instance-metadata-options` command if you need to make it larger. For example, you might need a larger hop limit for backward compatibility with container services running on the instance. For more information, see [modify-instance-metadata-options](#) in the *AWS CLI Command Reference*.

Transition to using Instance Metadata Service Version 2

Use of Instance Metadata Service Version 2 (IMDSv2) is optional. Instance Metadata Service Version 1 (IMDSv1) will continue to be supported indefinitely. If you choose to migrate to using IMDSv2, we recommend that you use the following tools and transition path.

Tools for helping with the transition to IMDSv2

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

- **AWS software:** The latest versions of the AWS SDKs and CLIs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the AWS SDKs and CLIs. For information about updating the CLI, see [Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide](#).
- **CloudWatch:** IMDSv2 uses token-backed sessions, while IMDSv1 does not. The `MetadataNoToken` CloudWatch metric tracks the number of calls to the instance metadata service that are using IMDSv1. By tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2. For more information, see [Instance metrics \(p. 978\)](#).
- **Updates to EC2 APIs and CLIs:** For existing instances, you can use the [modify-instance-metadata-options](#) CLI command (or the `ModifyInstanceMetadataOptions` API) to require the use of IMDSv2. For new instances, you can use the [run-instances](#) CLI command (or the `RunInstances` API) and the `metadata-options` parameter to launch new instances that require the use of IMDSv2.

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you [create a launch template](#) or [create a launch configuration](#), you must configure the `MetadataOptions` parameters to require the use of IMDSv2. After you configure the launch template or launch configuration, the Auto Scaling group launches new instances using the new launch template or launch configuration, but existing instances are not affected.

Use the [modify-instance-metadata-options](#) CLI command (or the `ModifyInstanceMetadataOptions` API) to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto Scaling group will launch new replacement instances with the instance metadata options settings that are defined in the launch template or launch configuration.

- **IAM policies and SCPs:** You can use an IAM condition to enforce that IAM users can't launch an instance unless it uses IMDSv2. You can also use IAM conditions to enforce that IAM users can't modify running instances to re-enable IMDSv1, and to enforce that the instance metadata service is available on the instance.

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and `ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the `RunInstances` and the [ModifyInstanceMetadataOptions](#) API and corresponding CLI. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an `UnauthorizedOperation` response. These condition keys can be used either in IAM policies or AWS Organizations service control policies (SCPs).

Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1 to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials, you can use a new condition key in either IAM policies or AWS Organizations service control policies (SCPs). Specifically, by using the policy condition key `ec2:RoleDelivery` with a value of `2.0` in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will receive an `UnauthorizedOperation` response. The same thing can be achieved more broadly with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot actually be used to call APIs because any API calls not matching the specified condition will receive an `UnauthorizedOperation` error. For example IAM policies, see [Work with instance metadata \(p. 1285\)](#). For more information, see [Service Control Policies](#) in the [AWS Organizations User Guide](#).

Recommended path to requiring IMDSv2 access

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2:

Step 1: At the start

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to IMDSv2-compatible versions. For information about updating the CLI, see [Upgrading to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Then, change your software that directly accesses instance metadata (in other words, that does not use an SDK) using the IMDSv2 requests.

Step 2: During the transition

Track your transition progress by using the CloudWatch metric `MetadataNoToken`. This metric shows the number of calls to the instance metadata service that are using IMDSv1 on your instances. For more information, see [Instance metrics \(p. 978\)](#).

Step 3: When everything is ready on all instances

Everything is ready on all instances when the CloudWatch metric `MetadataNoToken` records zero IMDSv1 usage. At this stage, you can do the following:

- For existing instances: You can require IMDSv2 use through the [modify-instance-metadata-options](#) command. You can make these changes on running instances; you do not need to restart your instances.
- For new instances: When launching a new instance, you can do one of the following:
 - In the Amazon EC2 console launch instance wizard, set **Metadata accessible** to **Enabled** and **Metadata version** to **V2**. For more information, see [Step 3: Configure Instance Details \(p. 582\)](#).
 - Use the [run-instances](#) command to specify that only IMDSv2 is to be used.

Updating instance metadata options for existing instances is available only through the API or AWS CLI. It is currently not available in the Amazon EC2 console. For more information, see [Configure the instance metadata options \(p. 730\)](#).

Step 4: When all of your instances are transitioned to IMDSv2

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and `ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the [RunInstances](#) and the [ModifyInstanceMetadataOptions](#) API and corresponding CLI. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an `UnauthorizedOperation` response. For example IAM policies, see [Work with instance metadata \(p. 1285\)](#).

Configure the instance metadata options

Instance metadata options allow you to configure new or existing instances to do the following:

- Require the use of IMDSv2 when requesting instance metadata
- Specify the `PUT` response hop limit
- Turn off access to instance metadata

You can also use IAM condition keys in an IAM policy or SCP to do the following:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops

- Turn off access to instance metadata

Note

You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:

- If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.
- If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.
- For IMDSv2, you must use `/latest/api/token` when retrieving the token.

- [Modify instance metadata options for existing instances \(p. 732\)](#)

Configure instance metadata options for new instances

You can require the use of IMDSv2 on an instance when you launch it. You can also create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.

Console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, select the following options on the [Configure Instance Details](#) page:
 - Under **Advanced Details**, for **Metadata accessible**, select **Enabled**.
 - For **Metadata version**, select **V2 (token required)**.

For more information, see [Step 3: Configure Instance Details \(p. 582\)](#).

AWS CLI

To require the use of IMDSv2 on a new instance subnet

The following `run-instances` example launches a `c3.large` instance with `--metadata-options` set to `HttpTokens=required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`. Because the secure token header is set to `required` for metadata retrieval requests, this opts in the instance to require using IMDSv2 when requesting instance metadata.

```
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --instance-type c3.large
  ...
  --metadata-options "HttpEndpoint=enabled,HttpTokens=required"
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the [AWS::EC2::LaunchTemplate MetadataOptions](#) property in the [AWS CloudFormation User Guide](#).

To enforce the use of IMDSv2 on all new instances

To ensure that IAM users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see [Work with instance metadata \(p. 1285\)](#).

Configure IPv4 and IPv6 endpoints

By default, the IPv6 endpoint is disabled. This is true even if you are launching an instance into an IPv6-only subnet. You can choose to enable this endpoint at instance launch. The IPv6 endpoint for IMDS is only accessible on [Instances built on the Nitro System \(p. 247\)](#). For more information about the metadata options, see [run-instances](#) in the *AWS CLI command reference*. The following example shows you how to enable the IPv6 endpoint for IMDS:

```
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --instance-type t3.large
  ...
  --metadata-options "HttpEndpoint=enabled,HttpProtocolIpv6=enabled"
```

Console

To turn off access to instance metadata

- To ensure that access to your instance metadata is turned off, regardless of which version of the instance metadata service you are using, launch the instance in the Amazon EC2 console with the following option selected on the **Configure Instance Details** page:
 - Under **Advanced Details**, for **Metadata accessible**, select **Disabled**.

For more information, see [Step 3: Configure Instance Details \(p. 582\)](#).

AWS CLI

To turn off access to instance metadata

To ensure that access to your instance metadata is turned off, regardless of which version of the instance metadata service you are using, launch the instance with `--metadata-options` set to `HttpEndpoint=disabled`. You can turn access on later by using the [modify-instance-metadata-options](#) command.

```
aws ec2 run-instances
  --image-id ami-0abcdef1234567890
  --instance-type c3.large
  ...
  --metadata-options "HttpEndpoint=disabled"
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the [AWS::EC2::LaunchTemplate MetadataOptions](#) property in the *AWS CloudFormation User Guide*.

Modify instance metadata options for existing instances

You can require the use IMDSv2 on an existing instance. You can also change the PUT response hop limit and turn off access to instance metadata on an existing instance. You can also create an IAM policy that prevents users from modifying the instance metadata options on an existing instance.

Currently only the AWS SDK or AWS CLI support modifying the instance metadata options on existing instances. You can't use the Amazon EC2 console for modifying instance metadata options.

To require the use of IMDSv2

You can opt in to require that IMDSv2 is used when requesting instance metadata. Use the [modify-instance-metadata-options](#) CLI command and set the `http-tokens` parameter to `required`. When you specify a value for `http-tokens`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-tokens required \
--http-endpoint enabled
```

To change the PUT response hop limit

For existing instances, you can change the settings of the PUT response hop limit. Use the [modify-instance-metadata-options](#) CLI command and set the `http-put-response-hop-limit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `http-put-response-hop-limit`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-put-response-hop-limit 3 \
--http-endpoint enabled
```

To restore the use of IMDSv1 on an instance using IMDSv2

You can use the [modify-instance-metadata-options](#) CLI command with `http-tokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-tokens optional \
--http-endpoint enabled
```

To turn on the IPv6 endpoint for your instance

By default, the IPv6 endpoint is disabled. This is true even if you have launched an instance into an IPv6-only subnet. The IPv6 endpoint for IMDS is only accessible on [Instances built on the Nitro System \(p. 247\)](#). For more information about the metadata options, see [modify-instance-metadata-options](#) in the *AWS CLI command reference*. The following example shows you how to turn on the IPv6 endpoint for the instance metadata service.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-protocol-ipv6 enabled \
--http-endpoint enabled
```

To turn off access to instance metadata

You can turn off access to your instance metadata by disabling the HTTP endpoint of the instance metadata service, regardless of which version of the instance metadata service you are using. You can reverse this change at any time by enabling the HTTP endpoint. Use the [modify-instance-metadata-options](#) CLI command and set the `http-endpoint` parameter to `disabled`.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-endpoint disabled
```

To control the use of modify-instance-metadata-options

To control which IAM users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the [ModifyInstanceMetadataOptions](#) API. For the example IAM policy, see [Work with instance metadata \(p. 1285\)](#).

Retrieve instance metadata

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you're writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

Instance metadata is divided into categories. For a description of each instance metadata category, see [Instance metadata categories \(p. 744\)](#).

To view all categories of instance metadata from within a running instance, use the following IPv4 or IPv6 URIs:

```
http://169.254.169.254/latest/meta-data/
```

This IPv4 address is a link-local address and it is valid only from the instance. For more information, see [Link-local address](#) on Wikipedia.

```
http://[fd00:ec2::254]/latest/meta-data/
```

The IP addresses are link-local address and are valid only from the instance. For more information, see [Link-local address](#) on Wikipedia.

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

The command format is different, depending on whether you use IMDSv1 or IMDSv2. By default, you can use both instance metadata services. To require the use of IMDSv2, see [Use IMDSv2 \(p. 727\)](#).

You can use a tool such as cURL, as shown in the following example.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/
```

Note that you are not billed for HTTP requests used to retrieve instance metadata and user data.

Considerations

To avoid problems with instance metadata retrieval, consider the following:

- The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, the SDK retries the call and, if still unsuccessful, uses IMDSv1. This can result in a delay. In a container environment, if the hop limit is 1, the IMDSv2 response does not return because going to the container is considered an additional network hop. To avoid the process of falling back to IMDSv1 and the resultant delay, in a container environment we recommend that you set the hop limit to 2. For more information, see [Configure the instance metadata options \(p. 730\)](#).
- For IMDSv2, you must use /latest/api/token when retrieving the token. Issuing PUT requests to any version-specific path, for example /2021-03-23/api/token, will result in the metadata service returning 403 Forbidden errors. This behavior is intended.

Responses and error messages

All instance metadata is returned as text (HTTP content type text/plain).

A request for a specific metadata resource returns the appropriate value, or a 404 – Not Found HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a 404 – Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

For requests made using Instance Metadata Service Version 2, the following HTTP error codes can be returned:

- 400 – Missing or Invalid Parameters – The PUT request is not valid.
- 401 – Unauthorized – The GET request uses an invalid token. The recommended action is to generate a new token.
- 403 – Forbidden – The request is not allowed or the instance metadata service is turned off.

Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. These versions do not necessarily correlate with an Amazon EC2 API version. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

Query throttling

We throttle queries to the instance metadata service on a per-instance basis, and we place limits on the number of simultaneous connections from an instance to the instance metadata service.

If you're using the instance metadata service to retrieve AWS security credentials, avoid querying for credentials during every transaction or concurrently from a high number of threads or processes, as this might lead to throttling. Instead, we recommend that you cache the credentials until they start approaching their expiry time.

If you are throttled while accessing the instance metadata service, retry your query with an exponential backoff strategy.

Limit instance metadata service access

You can consider using local firewall rules to disable access from some or all processes to the instance metadata service.

Note

For [Instances built on the Nitro System \(p. 247\)](#), IMDS can be reached from your own network when a network appliance within your VPC, such as a virtual router, forwards packets to the IMDS address, and the default [source/destination check](#) on the instance is disabled. To prevent a source from outside your VPC reaching IMDS, we recommend that you modify the configuration of the network appliance to drop packets with the destination IPv4 address of IMDS 169.254.169.254 and, if you enabled the IPv6 endpoint, the IPv6 address of IMDS fd00:ec2::254.

Using iptables to limit access

The following example uses Linux iptables and its `owner` module to prevent the Apache webserver (based on its default installation user ID of `apache`) from accessing 169.254.169.254. It uses a *deny rule* to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner --uid-owner apache --jump REJECT
```

Or, you can consider only allowing access to particular users or groups, by using *allow rules*. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use *allow rules*, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to the instance metadata service by all processes, except for processes running in the user account `trustworthy-user`.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner ! --uid-owner trustworthy-user --jump REJECT
```

Note

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- By default, iptables rules are not persistent across system reboots. They can be made to be persistent by using OS features, not described here.
- The iptables `owner` module only matches group membership if the group is the primary group of a given local user. Other groups are not matched.

Using PF or IPFW to limit access

If you are using FreeBSD or OpenBSD, you can also consider using PF or IPFW. The following examples limit access to the instance metadata service to just the root user.

PF

```
$ block out inet proto tcp from any to 169.254.169.254
```

```
$ pass out inet proto tcp from any to 169.254.169.254 user root
```

IPFW

```
$ allow tcp from any to 169.254.169.254 uid root
```

```
$ deny tcp from any to 169.254.169.254
```

Note

The order of the PF and IPFW commands matter. PF defaults to last matching rule and IPFW defaults to first matching rule.

Work with instance user data

When working with instance user data, keep the following in mind:

- User data must be base64-encoded. The Amazon EC2 console can perform the base64-encoding for you or accept base64-encoded input.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length n after base64-encoding is $\text{ceil}(n/3)*4$.
- User data must be base64-decoded when you retrieve it. If you retrieve the data using instance metadata or the console, it's decoded for you automatically.
- User data is treated as opaque data: what you give is what you get back. It is up to the instance to be able to interpret it.
- If you stop an instance, modify its user data, and start the instance, the updated user data is not run when you start the instance.

Specify instance user data at launch

You can specify user data when you launch an instance. For more information, see [Launch an instance using the Launch Instance Wizard \(p. 580\)](#) and [Run commands on your Linux instance at launch \(p. 720\)](#).

Modify instance user data

You can modify user data for an instance in the stopped state if the root volume is an EBS volume. For more information, see [View and update the instance user data \(p. 722\)](#).

Retrieve instance user data

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

To retrieve user data from within a running instance, use the following URI.

```
http://169.254.169.254/latest/user-data

Retrieve dynamic data

To retrieve dynamic data from within a running instance, use the following URI.

```
http://169.254.169.254/latest/dynamic/
```

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

Instance metadata categories

Instance metadata is divided into categories. When you retrieve instance metadata, these are the top-level items.

When Amazon EC2 releases a new instance metadata category, the instance metadata for the new category might not be available for existing instances. With instances built on the [Nitro system \(p. 247\)](#), you can retrieve instance metadata only for the categories that were available at launch. For instances with the Xen hypervisor, you can [stop and then start \(p. 637\)](#) the instance to update the categories that are available for the instance.

The following table lists the categories of instance metadata. Some of the category names include placeholders for data that is unique to your instance. For example, *mac* represents the MAC address for the network interface. You must replace the placeholders with actual values when you retrieve the instance metadata.

Data	Description	Version
ami-id	The AMI ID used to launch the instance.	1.0
ami-launch-index	If you started more than one instance at the same time, this value indicates the order in which the instance was launched. The value of the first instance launched is 0.	1.0
ami-manifest-path	The path to the AMI manifest file in Amazon S3. If you used an Amazon EBS-backed AMI to launch the instance, the returned result is unknown.	1.0

Data	Description	Version
ancestor-ami-ids	The AMI IDs of any instances that were rebundled to create this AMI. This value will only exist if the AMI manifest file contained an <code>ancestor-amis</code> key.	2007-10-10
block-device-mapping/ami	The virtual device that contains the root/boot file system.	2007-12-15
block-device-mapping/ebs <i>N</i>	The virtual devices associated with any Amazon EBS volumes. Amazon EBS volumes are only available in metadata if they were present at launch time or when the instance was last started. The <i>N</i> indicates the index of the Amazon EBS volume (such as <code>ebs1</code> or <code>ebs2</code>).	2007-12-15
block-device-mapping/eph emeral <i>N</i>	The virtual devices for any non-NVMe instance store volumes. The <i>N</i> indicates the index of each volume. The number of instance store volumes in the block device mapping might not match the actual number of instance store volumes for the instance. The instance type determines the number of instance store volumes that are available to an instance. If the number of instance store volumes in a block device mapping exceeds the number available to an instance, the additional instance store volumes are ignored.	2007-12-15
block-device-mapping/root	The virtual devices or partitions associated with the root devices or partitions on the virtual device, where the root (/ or C:) file system is associated with the given instance.	2007-12-15
block-device-mapping/swap	The virtual devices associated with swap. Not always present.	2007-12-15
elastic-gpus/ associations/ <i>elastic-gpu-id</i>	If there is an Elastic GPU attached to the instance, contains a JSON string with information about the Elastic GPU, including its ID and connection information.	2016-11-30
elastic-inference/ associations/ <i>ei-a-id</i>	If there is an Elastic Inference accelerator attached to the instance, contains a JSON string with information about the Elastic Inference accelerator, including its ID and type.	2018-11-29

Data	Description	Version
events/maintenance/history	If there are completed or canceled maintenance events for the instance, contains a JSON string with information about the events. For more information, see To view event history about completed or canceled events (p. 955) .	2018-08-17
events/maintenance/scheduled	If there are active maintenance events for the instance, contains a JSON string with information about the events. For more information, see View scheduled events (p. 952) .	2018-08-17
events/recommendations/rebalance	The approximate time, in UTC, when the EC2 instance rebalance recommendation notification is emitted for the instance. The following is an example of the metadata for this category: { "noticeTime": "2020-11-05T08:22:00Z" }. This category is available only after the notification is emitted. For more information, see EC2 instance rebalance recommendations (p. 472) .	2020-11-04
hostname	If the EC2 instance is using IP-based naming (IPBN), this is the private IPv4 DNS hostname of the instance. If the EC2 instance is using Resource-based naming (RBN), this is the RBN. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). For more information about IPBN and RBN, see Amazon EC2 instance hostname types (p. 1053) .	2021-01-03
iam/info	If there is an IAM role associated with the instance, contains information about the last time the instance profile was updated, including the instance's LastUpdated date, InstanceProfileArn, and InstanceProfileId. Otherwise, not present.	2012-01-12

Data	Description	Version
<code>iam/security-credentials/ role-name</code>	If there is an IAM role associated with the instance, <code>role-name</code> is the name of the role, and <code>role-name</code> contains the temporary security credentials associated with the role (for more information, see Retrieve security credentials from instance metadata (p. 1298)). Otherwise, not present.	2012-01-12
<code>identity-credentials/ec2/ info</code>	[Internal use only] Information about the credentials in <code>identity-credentials/ec2/security-credentials/ec2-instance</code> . These credentials are used by AWS features such as EC2 Instance Connect, and do not have any additional AWS API permissions or privileges beyond identifying the instance.	2018-05-23
<code>identity-credentials/ec2/ security-credentials/ec2- instance</code>	[Internal use only] Credentials that allow on-instance software to identify itself to AWS to support features such as EC2 Instance Connect. These credentials do not have any additional AWS API permissions or privileges.	2018-05-23
<code>instance-action</code>	Notifies the instance that it should reboot in preparation for bundling. Valid values: <code>none</code> <code>shutdown</code> <code>bundle-pending</code> .	2008-09-01
<code>instance-id</code>	The ID of this instance.	Version 1.0
<code>instance-life-cycle</code>	The purchasing option of this instance. For more information, see Instance purchasing options (p. 390) .	2019-10-01
<code>instance-type</code>	The type of instance. For more information, see Instance types (p. 240) .	2007-08-29
<code>ipv6</code>	The IPv6 address of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0) network interface and the first IPv6 address assigned. If no IPv6 address exists on network interface[0], this item is not set and results in an HTTP 404 response.	2021-01-03

Data	Description	Version
kernel-id	The ID of the kernel launched with this instance, if applicable.	2008-02-01
local-hostname	In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If the EC2 instance is using IP-based naming (IPBN), this is the private IPv4 DNS hostname of the instance. If the EC2 instance is using Resource-based naming (RBN), this is the RBN. For more information about IPBN, RBN, and EC2 instance naming, see Amazon EC2 instance hostname types (p. 1053) .	2021-01-03
local-ipv4	The private IPv4 address of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If this is an IPv6-only instance, this item is not set and results in an HTTP 404 response.	2021-01-03
mac	The instance's media access control (MAC) address. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0).	2011-01-01
metrics/vhostmd	No longer available.	2011-05-01
network/interfaces/macs/mac/device-number	The unique device number associated with that interface. The device number corresponds to the device name; for example, a device-number of 2 is for the eth2 device. This category corresponds to the DeviceIndex and device-index fields that are used by the Amazon EC2 API and the EC2 commands for the AWS CLI.	2011-01-01
network/interfaces/macs/mac/interface-id	The ID of the network interface.	2011-01-01
network/interfaces/macs/mac/ipv4-associations/public-ip	The private IPv4 addresses that are associated with each public IP address and assigned to that interface.	2011-01-01

Data	Description	Version
<code>network/interfaces/macs/mac/ipv6s</code>	The IPv6 addresses associated with the interface. Returned only for instances launched into a VPC.	2016-06-30
<code>network/interfaces/macs/mac/local-hostname</code>	The private IPv4 DNS hostname of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If this is a IPv6-only instance, this is the resource-based name. For more information about IPBN and RBN, see Amazon EC2 instance hostname types (p. 1053) .	2021-01-03
<code>network/interfaces/macs/mac/local-ipv4s</code>	The private IPv4 addresses associated with the interface. If this is an IPv6-only network interface, this item is not set and results in an HTTP 404 response.	2021-01-03
<code>network/interfaces/macs/mac/mac</code>	The instance's MAC address.	2011-01-01
<code>network/interfaces/macs/mac/network-card-index</code>	The index of the network card. Some instance types support multiple network cards.	2020-11-01
<code>network/interfaces/macs/mac/owner-id</code>	The ID of the owner of the network interface. In multiple-interface environments, an interface can be attached by a third party, such as Elastic Load Balancing. Traffic on an interface is always billed to the interface owner.	2011-01-01
<code>network/interfaces/macs/mac/public-hostname</code>	The interface's public DNS (IPv4). This category is only returned if the enableDnsHostnames attribute is set to true. For more information, see Using DNS with Your VPC in the <i>Amazon VPC User Guide</i> . If the instance only has a public-IPv6 address and no public-IPv4 address, this item is not set and results in an HTTP 404 response.	2021-01-03
<code>network/interfaces/macs/mac/public-ipv4s</code>	The public IP address or Elastic IP addresses associated with the interface. There may be multiple IPv4 addresses on an instance.	2011-01-01
<code>network/interfaces/macs/mac/security-groups</code>	Security groups to which the network interface belongs.	2011-01-01

Data	Description	Version
network/interfaces/macs/mac/security-group-ids	The IDs of the security groups to which the network interface belongs.	2011-01-01
network/interfaces/macs/mac/subnet-id	The ID of the subnet in which the interface resides.	2011-01-01
network/interfaces/macs/mac/subnet-ipv4-cidr-block	The IPv4 CIDR block of the subnet in which the interface resides.	2011-01-01
network/interfaces/macs/mac/subnet-ipv6-cidr-blocks	The IPv6 CIDR block of the subnet in which the interface resides.	2016-06-30
network/interfaces/macs/mac/vpc-id	The ID of the VPC in which the interface resides.	2011-01-01
network/interfaces/macs/mac/vpc-ipv4-cidr-block	The primary IPv4 CIDR block of the VPC.	2011-01-01
network/interfaces/macs/mac/vpc-ipv4-cidr-blocks	The IPv4 CIDR blocks for the VPC.	2016-06-30
network/interfaces/macs/mac/vpc-ipv6-cidr-blocks	The IPv6 CIDR block of the VPC in which the interface resides.	2016-06-30
placement/availability-zone	The Availability Zone in which the instance launched.	2008-02-01
placement/availability-zone-id	The static Availability Zone ID in which the instance is launched. The Availability Zone ID is consistent across accounts. However, it might be different from the Availability Zone, which can vary by account.	2020-08-24
placement/group-name	The name of the placement group in which the instance is launched.	2020-08-24
placement/host-id	The ID of the host on which the instance is launched. Applicable only to Dedicated Hosts.	2020-08-24
placement/partition-number	The number of the partition in which the instance is launched.	2020-08-24
placement/region	The AWS Region in which the instance is launched.	2020-08-24
product-codes	AWS Marketplace product codes associated with the instance, if any.	2007-03-01

Data	Description	Version
public-hostname	The instance's public DNS (IPv4). This category is only returned if the <code>enableDnsHostnames</code> attribute is set to <code>true</code> . For more information, see Using DNS with Your VPC in the <i>Amazon VPC User Guide</i> . If the instance only has a public-IPv6 address and no public-IPv4 address, this item is not set and results in an HTTP 404 response.	2021-01-03
public-ipv4	The public IPv4 address. If an Elastic IP address is associated with the instance, the value returned is the Elastic IP address.	2007-01-19
public-keys/0/openssh-key	Public key. Only available if supplied at instance launch time.	Version 1.0
ramdisk-id	The ID of the RAM disk specified at launch time, if applicable.	2007-10-10
reservation-id	The ID of the reservation.	Version 1.0
security-groups	<p>The names of the security groups applied to the instance.</p> <p>After launch, you can change the security groups of the instances. Such changes are reflected here and in <code>network/interfaces/macs/<i>mac</i>/security-groups</code>.</p>	Version 1.0
services/domain	The domain for AWS resources for the Region.	2014-02-25
services/partition	The partition that the resource is in. For standard AWS Regions, the partition is <code>aws</code> . If you have resources in other partitions, the partition is <code>aws-<i>partitionname</i></code> . For example, the partition for resources in the China (Beijing) Region is <code>aws-cn</code> .	2015-10-20
spot/instance-action	The action (hibernate, stop, or terminate) and the approximate time, in UTC, when the action will occur. This item is present only if the Spot Instance has been marked for hibernate, stop, or terminate. For more information, see instance-action (p. 482) .	2016-11-15

Data	Description	Version
spot/termination-time	The approximate time, in UTC, that the operating system for your Spot Instance will receive the shutdown signal. This item is present and contains a time value (for example, 2015-01-05T18:02:00Z) only if the Spot Instance has been marked for termination by Amazon EC2. The termination-time item is not set to a time if you terminated the Spot Instance yourself. For more information, see termination-time (p. 482) .	2014-11-05
tags/instance	The instance tags associated with the instance. Only available if you explicitly allow access to tags in instance metadata. For more information, see Allow access to tags in instance metadata (p. 1704) .	2021-09-30

Dynamic data categories

The following table lists the categories of dynamic data.

Data	Description	Version
fws/instance-monitoring	Value showing whether the customer has enabled detailed one-minute monitoring in CloudWatch. Valid values: enabled disabled	2009-04-04
instance-identity/document	JSON containing instance attributes, such as instance-id, private IP address, etc. See Instance identity documents (p. 755) .	2009-04-04
instance-identity/pkcs7	Used to verify the document's authenticity and content against the signature. See Instance identity documents (p. 755) .	2009-04-04
instance-identity/signature	Data that can be used by other parties to verify its origin and authenticity. See Instance identity documents (p. 755) .	2009-04-04

Example: AMI launch index value

This example demonstrates how you can use both user data and instance metadata to configure your instances.

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

Alice wants to launch four instances of her favorite database AMI, with the first acting as the original instance and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replica. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the `ami-launch-index` instance metadata value, which will be unique for each instance. If she starts more than one instance at the same time, the `ami-launch-index` indicates the order in which the instances were launched. The value of the first instance launched is 0.

Here is the user data that Alice has constructed.

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The `replicate-every=1min` data defines the first replica's configuration, `replicate-every=5min` defines the second replica's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (|) delimiting the data for the separate instances.

Alice launches four instances using the `run-instances` command, specifying the user data.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --count 4 \
  --instance-type t2.micro \
  --user-data "replicate-every=1min | replicate-every=5min | replicate-every=10min"
```

After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI ID: ami-0abcdef1234567890
- Reservation ID: r-1234567890abcabc0
- Public keys: none
- Security group name: default
- Instance type: t2.micro

However, each instance has certain unique metadata.

Instance 1

Metadata	Value
instance-id	i-1234567890abcdef0
ami-launch-index	0
public-hostname	ec2-203-0-113-25.compute-1.amazonaws.com
public-ipv4	67.202.51.223
local-hostname	ip-10-251-50-12.ec2.internal
local-ipv4	10.251.50.35

Instance 2

Metadata	Value
instance-id	i-0598c7d356eba48d7

Metadata	Value
ami-launch-index	1
public-hostname	ec2-67-202-51-224.compute-1.amazonaws.com
public-ipv4	67.202.51.224
local-hostname	ip-10-251-50-36.ec2.internal
local-ipv4	10.251.50.36

Instance 3

Metadata	Value
instance-id	i-0ee992212549ce0e7
ami-launch-index	2
public-hostname	ec2-67-202-51-225.compute-1.amazonaws.com
public-ipv4	67.202.51.225
local-hostname	ip-10-251-50-37.ec2.internal
local-ipv4	10.251.50.37

Instance 4

Metadata	Value
instance-id	i-1234567890abcdef0
ami-launch-index	3
public-hostname	ec2-67-202-51-226.compute-1.amazonaws.com
public-ipv4	67.202.51.226
local-hostname	ip-10-251-50-38.ec2.internal
local-ipv4	10.251.50.38

Alice can use the `ami-launch-index` value to determine which portion of the user data is applicable to a particular instance.

- She connects to one of the instances, and retrieves the `ami-launch-index` for that instance to ensure it is one of the replicas:

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/meta-data/api/token"
-H "X-aws-ec2-metadata-token-ttl-seconds: 21600" \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-
data/ami-launch-index
2
```

For the following steps, the IMDSv2 requests use the stored token from the preceding IMDSv2 command, assuming the token has not expired.

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/ami-launch-index  
2
```

2. She saves the `ami-launch-index` as a variable.

IMDSv2

```
[ec2-user ~]$ ami_launch_index=`curl -H "X-aws-ec2-metadata-token: $TOKEN" -v  
http://169.254.169.254/latest/meta-data/ami-launch-index`
```

IMDSv1

```
[ec2-user ~]$ ami_launch_index=`curl http://169.254.169.254/latest/meta-data/ami-  
launch-index`
```

3. She saves the user data as a variable.

IMDSv2

```
[ec2-user ~]$ user_data=`curl -H "X-aws-ec2-metadata-token: $TOKEN" -v  
http://169.254.169.254/latest/user-data`
```

IMDSv1

```
[ec2-user ~]$ user_data=`curl http://169.254.169.254/latest/user-data`
```

4. Finally, Alice uses the `cut` command to extract the portion of the user data that is applicable to that instance.

IMDSv2

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"  
replicate-every=5min
```

IMDSv1

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index"  
replicate-every=5min
```

Instance identity documents

Each instance that you launch has an instance identity document that provides information about the instance itself. You can use the instance identity document to validate the attributes of the instance.

The instance identity document is generated when the instance is stopped and started, restarted, or launched. The instance identity document is exposed (in plaintext JSON format) through the Instance Metadata Service. The IPv4 address 169.254.169.254 is a link-local address and is valid only from the instance. For more information, see [Link-local address](#) on Wikipedia. The IPv6 address fd00:ec2::254 is a unique local address and is valid only from the instance. For more information, see [Unique local address](#) on Wikipedia.

Note

The examples in this section use the IPv4 address of the instance metadata service: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 247\)](#).

You can retrieve the instance identity document from a running instance at any time. The instance identity document includes the following information:

Data	Description
devpayProductCodes	Deprecated.
marketplaceProductCode	The AWS Marketplace product code of the AMI used to launch the instance.
availabilityZone	The Availability Zone in which the instance is running.
privateIp	The private IPv4 address of the instance.
version	The version of the instance identity document format.
instanceId	The ID of the instance.
billingProducts	The billing products of the instance.
instanceType	The instance type of the instance.
accountId	The ID of the AWS account that launched the instance.
imageId	The ID of the AMI used to launch the instance.
pendingTime	The date and time that the instance was launched.
architecture	The architecture of the AMI used to launch the instance (i386 x86_64 arm64).
kernelId	The ID of the kernel associated with the instance, if applicable.
ramdiskId	The ID of the RAM disk associated with the instance, if applicable.
region	The Region in which the instance is running.

Retrieve the plaintext instance identity document

To retrieve the plaintext instance identity document

Connect to the instance and run one of the following commands depending on the Instance Metadata Service (IMDS) version used by the instance.

IMDSv2

```
$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/dynamic/
instance-identity/document
```

IMDSv1

```
$ curl http://169.254.169.254/latest/dynamic/instance-identity/document
```

The following is example output.

```

Verify the instance identity document

If you intend to use the contents of the instance identity document for an important purpose, you should verify its contents and authenticity before using it.

The plaintext instance identity document is accompanied by three hashed and encrypted signatures. You can use these signatures to verify the origin and authenticity of the instance identity document and the information that it includes. The following signatures are provided:

- Base64-encoded signature—This is a base64-encoded SHA256 hash of the instance identity document that is encrypted using an RSA key pair.
- PKCS7 signature—This is a SHA1 hash of the instance identity document that is encrypted using a DSA key pair.
- RSA-2048 signature—This is a SHA256 hash of the instance identity document that is encrypted using an RSA-2048 key pair.

Each signature is available at a different endpoint in the instance metadata. You can use any one of these signatures depending on your hashing and encryption requirements. To verify the signatures, you must use the corresponding AWS public certificate.

The following topics provide detailed steps for validating the instance identity document using each signature.

- [Use the PKCS7 signature to verify the instance identity document \(p. 757\)](#)
- [Use the base64-encoded signature to verify the instance identity document \(p. 761\)](#)
- [Use the RSA-2048 signature to verify the instance identity document \(p. 765\)](#)

Use the PKCS7 signature to verify the instance identity document

This topic explains how to verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate.

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata and add it to a new file named `pkcs7` along with the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ echo "-----BEGIN PKCS7-----" >> pkcs7 \
&& TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
metadata-token-ttl-seconds: 21600"` \

5. Use the **OpenSSL smime** command to verify the signature. Include the **-verify** option to indicate that the signature needs to be verified, and the **-noverify** option to indicate that the certificate does not need to be verified.

```
$ openssl smime -verify -in pkcs7 -inform PEM -content document -certfile certificate -  
noverify
```

If the signature is valid, the `Verification successful` message appears. If the signature cannot be verified, contact AWS Support.

Use the base64-encoded signature to verify the instance identity document

This topic explains how to verify the instance identity document using the base64-encoded signature and the AWS RSA public certificate.

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to binary, and add it to a file named `signature`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-  
metadata-token-ttl-seconds: 21600" ` \  
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/  
dynamic/instance-identity/signature | base64 -d >> signature
```

IMDSv1

```
$ curl -s http://169.254.169.254/latest/dynamic/instance-identity/signature |  
base64 -d >> signature
```

3. Retrieve the plaintext instance identity document from the instance metadata and add it to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-  
metadata-token-ttl-seconds: 21600" ` \\  
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/  
dynamic/instance-identity/document >> document
```

IMDSv1

```
$ curl -s http://169.254.169.254/latest/dynamic/instance-identity/document  
>> document
```

4. Add the AWS RSA public certificate to a new file named `certificate`. Use one of the following commands, depending on the Region of your instance.

The following AWS public certificate is for all AWS Regions, except Hong Kong, Bahrain, China, and GovCloud.

5. Extract the public key from the AWS RSA public certificate and save it to a file named `key`.

```
$ openssl x509 -pubkey -noout -in certificate >> key
```

6. Use **OpenSSL dgst** command to verify the instance identity document.

```
$ openssl dgst -sha256 -verify key -signature signature document
```

If the signature is valid, the `Verified OK` message appears. If the signature cannot be verified, contact AWS Support.

Use the RSA-2048 signature to verify the instance identity document

This topic explains how to verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate.

To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata and add it to a file named `rsa2048` along the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048 \
&& TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/
dynamic/instance-identity/rsa2048 >> rsa2048 \
&& echo "" >> rsa2048 \
&& echo "-----END PKCS7-----" >> rsa2048
```

IMDSv1

```
$ echo "-----BEGIN PKCS7-----" >> rsa2048 \
&& curl -s http://169.254.169.254/latest/dynamic/instance-identity/rsa2048
>> rsa2048 \
&& echo "" >> rsa2048 \
&& echo "-----END PKCS7-----" >> rsa2048
```

3. Add the contents of the instance identity document from the instance metadata to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/
dynamic/instance-identity/document >> document
```

IMDSv1

```
$ curl -s http://169.254.169.254/latest/dynamic/instance-identity/document
>> document
```

4. Add the AWS RSA-2048 public certificate for your Region to a new file named `certificate`. Use one of the following commands depending on the Region of your instance.

Amazon Elastic Inference

Amazon Elastic Inference (EI) is a resource you can attach to your Amazon EC2 CPU instances to accelerate your deep learning (DL) inference workloads. Amazon EI accelerators come in multiple sizes and are a cost-effective method to build intelligent capabilities into applications running on Amazon EC2 instances.

Amazon EI distributes model operations defined by TensorFlow, Apache MXNet, PyTorch, and the Open Neural Network Exchange (ONNX) format through MXNet between low-cost, DL inference accelerators and the CPU of the instance.

For more information about Amazon Elastic Inference, see the [Amazon EI Developer Guide](#).

Identify EC2 Linux instances

Your application might need to determine whether it is running on an EC2 instance.

For information about identifying Windows instances, see [Identify EC2 Windows instances](#) in the *Amazon EC2 User Guide for Windows Instances*.

Inspect the instance identity document

For a definitive and cryptographically verified method of identifying an EC2 instance, check the instance identity document, including its signature. These documents are available on every EC2 instance at the local, non-routable address `http://169.254.169.254/latest/dynamic/instance-identity/`. For more information, see [Instance identity documents \(p. 755\)](#).

Inspect the system UUID

You can get the system UUID and look for the presence of the characters "ec2" or "EC2" in the beginning octet of the UUID. This method to determine whether a system is an EC2 instance is quick but potentially inaccurate because there is a small chance that a system that is not an EC2 instance could have a UUID that starts with these characters. Furthermore, for EC2 instances that are not using Amazon Linux 2, the distribution's implementation of SMBIOS might represent the UUID in little-endian format, therefore the "EC2" characters do not appear at the beginning of the UUID.

Example : Get the UUID from DMI (HVM AMIs only)

Use the following command to get the UUID using the Desktop Management Interface (DMI):

```
[ec2-user ~]$ sudo dmidecode --string system-uuid
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2E1916-9099-7CAF-FD21-012345ABCDEF
```

In the following example output, the UUID is represented in little-endian format.

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

Alternatively, for instances built on the Nitro system, you can use the following command:

```
[ec2-user ~]$ cat /sys/devices/virtual/dmi/id/board_asset_tag
```

If the output is an instance ID, as the following example output, the system is an EC2 instance:

```
i-0af01c0123456789a
```

Example : Get the UUID from the hypervisor (PV AMIs only)

Use the following command to get the UUID from the hypervisor:

```
[ec2-user ~]$ cat /sys/hypervisor/uuid
```

In the following example output, the UUID starts with "ec2", which indicates that the system is probably an EC2 instance.

```
ec2e1916-9099-7caf-fd21-012345abcdef
```

EC2 Fleet and Spot Fleet

You can use an EC2 Fleet or a Spot Fleet to launch a fleet of instances. In a single API call, a fleet can launch multiple instance types across multiple Availability Zones, using the On-Demand Instance, Reserved Instance, and Spot Instance purchasing options together.

EC2 Fleet

An *EC2 Fleet* contains the configuration information to launch a fleet—or group—of instances. In a single API call, a fleet can launch multiple instance types across multiple Availability Zones, using the On-Demand Instance, Reserved Instance, and Spot Instance purchasing options together. Using EC2 Fleet, you can:

- Define separate On-Demand and Spot capacity targets and the maximum amount you’re willing to pay per hour
- Specify the instance types that work best for your applications
- Specify how Amazon EC2 should distribute your fleet capacity within each purchasing option

You can also set a maximum amount per hour that you’re willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity specified in your request. If you specified a total maximum price per hour, it fulfills the capacity until it reaches the maximum amount that you’re willing to pay. The fleet can also attempt to maintain its target Spot capacity if your Spot Instances are interrupted. For more information, see [How Spot Instances work \(p. 444\)](#).

You can specify an unlimited number of instance types per EC2 Fleet. Those instance types can be provisioned using both On-Demand and Spot purchasing options. You can also specify multiple Availability Zones, specify different maximum Spot prices for each instance, and choose additional Spot options for each fleet. Amazon EC2 uses the specified options to provision capacity when the fleet launches.

While the fleet is running, if Amazon EC2 reclaims a Spot Instance because of a price increase or instance failure, EC2 Fleet can try to replace the instances with any of the instance types that you specify. This makes it easier to regain capacity during a spike in Spot pricing. You can develop a flexible and elastic resourcing strategy for each fleet. For example, within specific fleets, your primary capacity can be On-Demand supplemented with less-expensive Spot capacity if available.

If you have Reserved Instances and you specify On-Demand Instances in your fleet, EC2 Fleet uses your Reserved Instances. For example, if your fleet specifies an On-Demand Instance as `c4.large`, and you have Reserved Instances for `c4.large`, you receive the Reserved Instance pricing.

There is no additional charge for using EC2 Fleet. You pay only for the EC2 instances that the fleet launches for you.

EC2 Fleet limitations

The following limitations apply to EC2 Fleet:

- EC2 Fleet is available only through the API or AWS CLI.
- An EC2 Fleet request can't span AWS Regions. You need to create a separate EC2 Fleet for each Region.
- An EC2 Fleet request can't span different subnets from the same Availability Zone.

Burstable performance instances

If you launch your Spot Instances using a [burstable performance instance type \(p. 266\)](#), and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in [Standard mode \(p. 281\)](#) to avoid paying higher costs. If you launch burstable performance Spot Instances in [Unlimited mode \(p. 274\)](#) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see [When to use unlimited mode versus fixed CPU \(p. 276\)](#).

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use [Unlimited mode \(p. 274\)](#) for T2 Spot Instances, or use an instance type with dedicated CPU.

EC2 Fleet request types

There are three types of EC2 Fleet requests:

instant

If you configure the request type as `instant`, EC2 Fleet places a synchronous one-time request for your desired capacity. In the API response, it returns the instances that launched, along with errors for those instances that could not be launched. For more information, see [Use an EC2 Fleet of type 'instant' \(p. 780\)](#).

request

If you configure the request type as `request`, EC2 Fleet places an asynchronous one-time request for your desired capacity. Thereafter, if capacity is diminished because of Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable.

maintain

(Default) If you configure the request type as `maintain`, EC2 Fleet places an asynchronous request for your desired capacity, and maintains capacity by automatically replenishing any interrupted Spot Instances.

All three types of requests benefit from an allocation strategy. For more information, see [Allocation strategies for Spot Instances \(p. 799\)](#).

Use an EC2 Fleet of type 'instant'

The EC2 Fleet of type `instant` is a synchronous one-time request that makes only one attempt to launch your desired capacity. The API response lists the instances that launched, along with errors for those instances that could not be launched. There are several benefits to using an EC2 Fleet of type `instant`, which are described in this article. Example configurations are provided at the end of the article.

For workloads that need a launch-only API to launch EC2 instances, you can use the `RunInstances` API. However, with `RunInstances`, you can only launch On-Demand Instances or Spot Instances, but not both in the same request. Furthermore, when you use `RunInstances` to launch Spot Instances, your Spot Instance request is limited to one instance type and one Availability Zone. This targets a single Spot capacity pool (a set of unused instances with the same instance type and Availability Zone). If the Spot capacity pool does not have sufficient Spot Instance capacity for your request, the `RunInstances` call fails.

Instead of using `RunInstances` to launch Spot Instances, we recommend that you rather use the `CreateFleet` API with the `type` parameter set to `instant` for the following benefits:

- **Launch On-Demand Instances and Spot Instances in one request.** An EC2 Fleet can launch On-Demand Instances, Spot Instances, or both. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price.
- **Increase the availability of Spot Instances.** By using an EC2 Fleet of type `instant`, you can launch Spot Instances following [Spot best practices](#) with the resulting benefits:
 - **Spot best practice: Be flexible about instance types and Availability Zones.**

Benefit: By specifying several instance types and Availability Zones, you increase the number of Spot capacity pools. This gives the Spot service a better chance of finding and allocating your desired Spot compute capacity. A good rule of thumb is to be flexible across at least 10 instance types for each workload and make sure that all Availability Zones are configured for use in your VPC.

- **Spot best practice: Use the capacity-optimized allocation strategy.**

Benefit: The capacity-optimized allocation strategy automatically provisions instances from the most-available Spot capacity pools. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances will be interrupted when Amazon EC2 needs the capacity back.

- **Get access to a wider set of capabilities.** For workloads that need a launch-only API, and where you prefer to manage the lifecycle of your instance rather than let EC2 Fleet manage it for you, use the EC2 Fleet of type `instant` instead of the [RunInstances](#) API. EC2 Fleet provides a wider set of capabilities than RunInstances, as demonstrated in the following examples. For all other workloads, you should use Amazon EC2 Auto Scaling because it supplies a more comprehensive feature set for a wide variety of workloads, like ELB-backed applications, containerized workloads, and queue processing jobs.

AWS services like Amazon EC2 Auto Scaling and Amazon EMR use EC2 Fleet of type `instant` to launch EC2 instances.

Prerequisites for EC2 Fleet of type instant

For the prerequisites for creating an EC2 Fleet, see [EC2 Fleet prerequisites \(p. 822\)](#).

How instant EC2 Fleet works

When working with an EC2 Fleet of type `instant`, the sequence of events is as follows:

1. Configure the [CreateFleet](#) request type as `instant`. For more information, see [Create an EC2 Fleet \(p. 828\)](#). Note that after you make the API call, you can't modify it.
2. When you make the API call, EC2 Fleet places a synchronous one-time request for your desired capacity.
3. The API response lists the instances that launched, along with errors for those instances that could not be launched.
4. You can describe your EC2 Fleet, list the instances associated with your EC2 Fleet, and view the history of your EC2 Fleet.
5. After your instances have launched, you can [delete the fleet request](#). When deleting the fleet request, you can also choose to terminate the associated instances, or leave them running.
6. You can terminate the instances at any time.

Examples

The following examples show how to use EC2 Fleet of type `instant` for different use cases. For more information about using the EC2 CreateFleet API parameters, see [CreateFleet](#) in the *Amazon EC2 API Reference*.

Example 1: Launch Spot Instances with the capacity-optimized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type `instant`: a launch template, target capacity, default purchasing option, and launch template overrides.

- The launch template is identified by its launch template name and version number.
- The 12 launch template overrides specify 4 different instance types and 3 different subnets, each in a separate Availability Zone. Each instance type and subnet combination defines a Spot capacity pool, resulting in 12 Spot capacity pools.
- The target capacity for the fleet is 20 instances.
- The default purchasing option is `spot`, which results in the fleet attempting to launch 20 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

Example 2: Launch a single Spot Instance with the capacity-optimized allocation strategy

You can optimally launch one Spot Instance at a time by making multiple EC2 Fleet API calls of type instant, by setting the TotalTargetCapacity to 1.

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch template overrides have 4 different instance types and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 1 instance, and the default purchasing option is spot, which results in the fleet attempting to launch a Spot Instance from one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy, to launch a Spot Instance from the most-available capacity pool.

Example 3: Launch Spot Instances using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight based on how many units of the workload can run on the instance assuming a unit of the workload requires a 15 GB of memory and 4 vCPUs. For example an m5.xlarge (4 vCPUs and 16 GB of memory) can run one unit and is weighted 1, m5.2xlarge (8 vCPUs and 32 GB of memory) can run 2 units and is weighted 2, and so on. The total target capacity is set to 40 units. The default purchasing option is spot, and the allocation strategy is capacity-optimized, which results in either 40 m5.xlarge (40 divided by 1), 20 m5.2xlarge (40 divided by 2), 10 m5.4xlarge (40 divided by 4), 5 m5.8xlarge (40 divided by 8), or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

[Example 8: Launch instances with multiple Launch Templates](#)

You can configure a fleet to launch instances with different launch specifications for different instance types or a group of instance types, by specifying multiple launch templates. In this example we want have different EBS volume sizes for different instance types and we have that configured in the launch templates ec2-fleet-lt-4xl, ec2-fleet-lt-9xl and ec2-fleet-lt-18xl.

In this example, we are using 3 different launch templates for the 3 instance types based on their size. The launch specification overrides on all the launch templates use instance weights based on the vCPUs on the instance type. The total target capacity is 144 units, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet can either launch 9 c5n.4xlarge (144 divided by 16) using the launch template ec2-fleet-4xl or 4 c5n.9xlarge (144 divided by 36) using the launch template ec2-fleet-9xl, or 2 c5n.18xlarge (144 divided by 72) using the launch template ec2-fleet-18xl, or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

Example 9: Launch Spot Instance with a base of On-Demand Instances

The following example specifies the total target capacity of 20 instances for the fleet, and a target capacity of 5 On-Demand Instances. The default purchasing option is spot. The fleet launches 5 On-Demand Instance as specified, but needs to launch 15 more instances to fulfill the total target capacity. The purchasing option for the difference is calculated as `TotalTargetCapacity - OnDemandTargetCapacity = DefaultTargetCapacityType`, which results in the fleet launching 15 Spot Instances from one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy.

Example 10: Launch Spot Instances using capacity-optimized allocation strategy with a base of On-Demand Instances using Capacity Reservations and the prioritized allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching a base of On-Demand Instances with the default target capacity type as spot by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 6 available unused Capacity Reservations. This is less than the fleet's target On-Demand capacity of 10 On-Demand Instances.

The account has the following 6 unused Capacity Reservations in 2 pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",

}
```

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The Spot allocation strategy is capacity-optimized. The total target capacity is 20, the On-Demand target capacity is 10, and the default target capacity type is spot.

After you create the instant fleet using the preceding configuration, the following 20 instances are launched to meet the target capacity:

- 7 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized first, and there are 3 available unused c5.large Capacity Reservations. The Capacity Reservations are used first to launch 3 On-Demand Instances plus 4 additional On-Demand Instances are launched according to the On-Demand allocation strategy, which is prioritized in this example.
- 3 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is prioritized second, and there are 3 available unused c3.large Capacity Reservations.
- 10 Spot Instances from one of the 12 Spot capacity pools that has the optimal capacity according to the capacity-optimized allocation strategy.

After the fleet is launched, you can run [describe-capacity-reservations](#) to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the c5.large and m5.large Capacity Reservations were used.

Example 11: Launch Spot Instances using capacity-optimized-prioritized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch specifications which override the launch template have 4 different instance types with a priority assigned, and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 20 instances, and the default purchasing option is spot, which results in the fleet attempting to launch 20 Spot Instances from one of the 12 Spot capacity pools based on the capacity-optimized-prioritized allocation strategy, which implements priorities on a best-effort basis, but optimizes for capacity first.

EC2 Fleet configuration strategies

An *EC2 Fleet* is a group of On-Demand Instances and Spot Instances.

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity that you specify in the fleet request. The fleet can comprise only On-Demand Instances, only Spot Instances, or a combination of both On-Demand Instances and Spot Instances. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price. The fleet also attempts to maintain its target capacity if your Spot Instances are interrupted.

You can also set a maximum amount per hour that you're willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you're willing to pay is reached, the fleet stops launching instances even if it hasn't met the target capacity.

A *Spot capacity pool* is a set of unused EC2 instances with the same instance type and Availability Zone. When you create an EC2 Fleet, you can include multiple launch specifications, which vary by instance type, Availability Zone, subnet, and maximum price. The fleet selects the Spot capacity pools that are used to fulfill the request, based on the launch specifications included in your request, and the configuration of the request. The Spot Instances come from the selected pools.

An EC2 Fleet enables you to provision large amounts of EC2 capacity that makes sense for your application based on number of cores or instances, or amount of memory. For example, you can specify an EC2 Fleet to launch a target capacity of 200 instances, of which 130 are On-Demand Instances and the rest are Spot Instances.

Use the appropriate configuration strategies to create an EC2 Fleet that meets your needs.

Plan an EC2 Fleet

When planning your EC2 Fleet, we recommend that you do the following:

- Determine whether you want to create an EC2 Fleet that submits a synchronous or asynchronous one-time request for the desired target capacity, or one that maintains a target capacity over time. For more information, see [EC2 Fleet request types \(p. 780\)](#).
- Determine the instance types that meet your application requirements.
- If you plan to include Spot Instances in your EC2 Fleet, review [Spot Best Practices](#) before you create the fleet. Use these best practices when you plan your fleet so that you can provision the instances at the lowest possible price.
- Determine the target capacity for your EC2 Fleet. You can set target capacity in instances or in custom units. For more information, see [EC2 Fleet instance weighting \(p. 820\)](#).
- Determine what portion of the EC2 Fleet target capacity must be On-Demand capacity and Spot capacity. You can specify 0 for On-Demand capacity or Spot capacity, or both.
- Determine your price per unit, if you are using instance weighting. To calculate the price per unit, divide the price per instance hour by the number of units (or weight) that this instance represents. If you are not using instance weighting, the default price per unit is the price per instance hour.
- Determine the maximum amount per hour that you’re willing to pay for your fleet. For more information, see [Control spending \(p. 819\)](#).
- Review the possible options for your EC2 Fleet. For information about the fleet parameters, see [create-fleet](#) in the *AWS CLI Command Reference*. For EC2 Fleet configuration examples, see [EC2 Fleet example configurations \(p. 917\)](#).

Allocation strategies for Spot Instances

The allocation strategy for your EC2 Fleet determines how it fulfills your request for Spot Instances from the possible Spot capacity pools represented by its launch specifications. The following are the allocation strategies that you can specify in your fleet:

`lowest-price`

The Spot Instances come from the Spot capacity pool with the lowest price. This is the default strategy.

`diversified`

The Spot Instances are distributed across all Spot capacity pools.

`capacity-optimized`

The Spot Instances come from the Spot capacity pool with optimal capacity for the number of instances that are launching. You can optionally set a priority for each instance type in your fleet using `capacity-optimized-prioritized`. EC2 Fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The `capacity-optimized` strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads such as big data and analytics, image and media rendering, machine learning, and high performance computing that may have a higher cost of interruption associated with restarting work and checkpointing. By offering the possibility of fewer interruptions, the `capacity-optimized` strategy can lower the overall cost of your workload.

Alternatively, you can use the `capacity-optimized-prioritized` allocation strategy with a `priority` parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. EC2 Fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet’s ability to provision optimal capacity). This is a good option for workloads where

the possibility of disruption must be minimized and the preference for certain instance types matters. Using priorities is supported only if your fleet uses a launch template. Note that when you set the priority for capacity-optimized-prioritized, the same priority is also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

InstancePoolsToUseCount

The Spot Instances are distributed across the number of Spot capacity pools that you specify. This parameter is valid only when used in combination with lowest-price.

Maintaining target capacity

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, an EC2 Fleet of type maintain launches replacement Spot Instances. If the allocation strategy is lowest-price, the fleet launches replacement instances in the pool where the Spot price is currently the lowest. If the allocation strategy is lowest-price in combination with InstancePoolsToUseCount, the fleet selects the Spot capacity pools with the lowest price and launches Spot Instances across the number of Spot capacity pools that you specify. If the allocation strategy is capacity-optimized, the fleet launches replacement instances in the pool that has the most available Spot Instance capacity. If the allocation strategy is diversified, the fleet distributes the replacement Spot Instances across the remaining pools.

Choose the appropriate allocation strategy

You can optimize your fleet based on your use case.

If your fleet runs workloads that may have a higher cost of interruption associated with restarting work and checkpointing, then use the capacity-optimized strategy. This strategy offers the possibility of fewer interruptions, which can lower the overall cost of your workload. Use the capacity-optimized-prioritized strategy for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

If your fleet is small or runs for a short time, the probability that your Spot Instances will be interrupted is low, even with all of the instances in a single Spot capacity pool. Therefore, the lowest-price strategy is likely to meet your needs while providing the lowest cost.

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing the Spot Instances across multiple pools using the diversified strategy. For example, if your EC2 Fleet specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is affected. Using this strategy also makes your fleet less sensitive to increases in the Spot price in any one pool over time. With the diversified strategy, the EC2 Fleet does not launch Spot Instances into any pools with a Spot price that is equal to or higher than the [On-Demand price](#).

To create a cheap and diversified fleet, use the lowest-price strategy in combination with InstancePoolsToUseCount. You can use a low or high number of Spot capacity pools across which to allocate your Spot Instances. For example, if you run batch processing, we recommend specifying a low number of Spot capacity pools (for example, InstancePoolsToUseCount=2) to ensure that your queue always has compute capacity while maximizing savings. If you run a web service, we recommend specifying a high number of Spot capacity pools (for example, InstancePoolsToUseCount=10) to minimize the impact if a Spot capacity pool becomes temporarily unavailable.

Configure EC2 Fleet for cost optimization

To optimize the costs for your use of Spot Instances, specify the lowest-price allocation strategy so that EC2 Fleet automatically deploys the least expensive combination of instance types and Availability Zones based on the current Spot price.

For On-Demand Instance target capacity, EC2 Fleet always selects the cheapest instance type based on the public On-Demand price, while continuing to follow the allocation strategy (either `lowest-price`, `capacity-optimized`, or `diversified`) for Spot Instances.

Configure EC2 Fleet for cost optimization and diversification

To create a fleet of Spot Instances that is both cheap and diversified, use the `lowest-price` allocation strategy in combination with `InstancePoolsToUseCount`. EC2 Fleet automatically deploys the least expensive combination of instance types and Availability Zones based on the current Spot price across the number of Spot capacity pools that you specify. This combination can be used to avoid the most expensive Spot Instances.

For example, if your target capacity is 10 Spot Instances, and you specify 2 Spot capacity pools (for `InstancePoolsToUseCount`), EC2 Fleet will draw on the two cheapest pools to fulfill your Spot capacity.

Note that EC2 Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, EC2 Fleet will continue to fulfill your request by drawing from the next cheapest pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

Configure EC2 Fleet for capacity optimization

To launch Spot Instances into the most-available Spot capacity pools, use the `capacity-optimized` allocation strategy. For an example configuration, see [Example 9: Launch Spot Instances in a capacity-optimized fleet \(p. 928\)](#).

You can also express your pool priorities by using the `capacity-optimized-prioritized` allocation strategy and then setting the order of instance types to use from highest to lowest priority. Using priorities is supported only if your fleet uses a launch template. Note that when you set priorities for `capacity-optimized-prioritized`, the same priorities are also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to `prioritized`. For an example configuration, see [Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities \(p. 929\)](#).

Attribute-based instance type selection for EC2 Fleet

When you create an EC2 Fleet, you must specify one or more instance types for configuring the On-Demand Instances and Spot Instances in the fleet. As an alternative to manually specifying the instance types, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. This is known as *attribute-based instance type selection*. For example, you can specify the minimum and maximum number of vCPUs required for your instances, and EC2 Fleet will launch the instances using any available instance types that meet those vCPU requirements.

Attribute-based instance type selection is ideal for workloads and frameworks that can be flexible about what instance types they use, such as when running containers or web fleets, processing big data, and implementing continuous integration and deployment (CI/CD) tooling.

Benefits

Attribute-based instance type selection has the following benefits:

- With so many instance types available, finding the right instance types for your workload can be time consuming. When you specify instance attributes, the instance types will automatically have the required attributes for your workload.

- To manually specify multiple instance types for an EC2 Fleet, you must create a separate launch template override for each instance type. But with attribute-based instance type selection, to provide multiple instance types, you need only specify the instance attributes in the launch template or in a launch template override.
- When you specify instance attributes rather than instance types, your fleet can use newer generation instance types as they're released, "future proofing" the fleet's configuration.
- When you specify instance attributes rather than instance types, EC2 Fleet can select from a wide range of instance types for launching Spot Instances, which adheres to the [Spot best practice of instance type flexibility \(p. 443\)](#).

How attribute-based instance type selection works

To use attribute-based instance type selection in your fleet configuration, you replace the list of instance types with a list of instance attributes that your instances require. EC2 Fleet will launch instances on any available instance types that have the specified instance attributes.

Types of instance attributes

There are several instance attributes that you can specify to express your compute requirements. For a description of each attribute and the default values, see [InstanceRequirements](#) in the *Amazon EC2 API Reference*.

Where to configure attribute-based instance type selection

Depending on whether you use the console or the AWS CLI, you can specify the instance attributes for attribute-based instance type selection as follows:

In the console, you can specify the instance attributes in one or both of the following fleet configuration components:

- In a launch template, and reference the launch template in the fleet request
- In the fleet request

In the AWS CLI, you can specify the instance attributes in one or all of the following fleet configuration components:

- In a launch template, and reference the launch template in the fleet request
- In a launch template override

If you want a mix of instances that use different AMIs, you can specify instance attributes in multiple launch template overrides. For example, different instance types can use x86 and Arm-based processors.

- In a launch specification

How EC2 Fleet uses attribute-based instance type selection when provisioning a fleet

EC2 Fleet provisions a fleet in the following way:

- EC2 Fleet identifies the instance types that have the specified attributes.
- EC2 Fleet uses price protection to determine which instance types to exclude.
- EC2 Fleet determines the capacity pools from which it will consider launching the instances based on the AWS Regions or Availability Zones that have matching instance types.
- EC2 Fleet applies the specified allocation strategy to determine from which capacity pools to launch the instances.

Note that attribute-based instance type selection does not pick the capacity pools from which to provision the fleet; that's the job of the allocation strategies. There might be a large number of instance types with the specified attributes, and some of them might be expensive. The default allocation strategy of `lowest-price` for Spot and On-Demand guarantees that EC2 Fleet will launch instances from the least expensive capacity pools.

If you specify an allocation strategy, EC2 Fleet will launch instances according to the specified allocation strategy.

- For Spot Instances, attribute-based instance type selection supports the `capacity-optimized` and `lowest-price` allocation strategies.
- For On-Demand Instances, attribute-based instance type selection supports the `lowest-price` allocation strategy.
- If there is no capacity for the instance types with the specified instance attributes, no instances can be launched, and the fleet returns an error.

Price protection

Price protection is a feature that prevents your EC2 Fleet from using instance types that you would consider too expensive even if they happen to fit the attributes that you specified. When you create a fleet with attribute-based instance type selection, price protection is enabled by default, with separate thresholds for On-Demand Instances and Spot Instances. When Amazon EC2 selects instance types with your attributes, it excludes instance types priced above your threshold. The thresholds represent the maximum you'll pay, expressed as a percentage above the least expensive M, C, or R instance type with your specified attributes.

If you don't specify a threshold, the following thresholds are used by default:

- For On-Demand Instances, the price protection threshold is set at 20 percent.
- For Spot Instances, the price protection threshold is set at 100 percent.

To specify the price protection threshold

While creating the EC2 Fleet, configure the fleet for attribute-based instance type selection, and then do the following:

- To specify the On-Demand Instance price protection threshold, in the JSON configuration file, in the `InstanceRequirements` structure, for `OnDemandMaxPricePercentageOverLowestPrice`, enter the price protection threshold as a percentage.

- To specify the Spot Instance price protection threshold, in the JSON configuration file, in the `InstanceRequirements` structure, for `SpotMaxPricePercentageOverLowestPrice`, enter the price protection threshold as a percentage.

For more information about creating the fleet, see [Create an EC2 Fleet with attribute-based instance type selection \(p. 804\)](#).

Note

When creating the EC2 Fleet, if you set `TargetCapacityUnitType` to `vcpu` or `memory-mib`, the price protection threshold is applied based on the per-vCPU or per-memory price instead of the per-instance price.

Considerations

- You can specify either instance types or instance attributes in an EC2 Fleet, but not both at the same time.

When using the CLI, the launch template overrides will override the launch template. For example, if the launch template contains an instance type and the launch template override contains instance attributes, the instances that are identified by the instance attributes will override the instance type in the launch template.

- When using the CLI, when you specify instance attributes as overrides, you can't also specify weights or priorities.
- You can specify a maximum of three `InstanceRequirements` structures in a request configuration.

Create an EC2 Fleet with attribute-based instance type selection

You can configure a fleet to use attribute-based instance type selection by using the AWS CLI.

Create an EC2 Fleet using the AWS CLI

To create an EC2 Fleet (AWS CLI)

- Use the [create-fleet](#) (AWS CLI) command to create an EC2 Fleet. Specify the fleet configuration in a JSON file.

```
aws ec2 create-fleet \
--region us-east-1 \
--cli-input-json file://file_name.json
```

The following JSON file contains all of the parameters that can be specified when configuring an EC2 Fleet. The parameters for attribute-based instance type selection are located in the `InstanceRequirements` structure. For a description of each attribute and the default values, see [InstanceRequirements in the Amazon EC2 API Reference](#).

Note

When `InstanceRequirements` is included in the fleet configuration, `InstanceType` and `WeightedCapacity` must be excluded; they cannot determine the fleet configuration at the same time as instance attributes.

Examples of configurations that are valid and not valid

If you use the AWS CLI to create an EC2 Fleet, you must make sure that your fleet configuration is valid. The following examples show configurations that are valid and not valid.

Configurations are considered not valid when they contain the following:

- A single `Overrides` structure with both `InstanceRequirements` and `InstanceType`
- Two `Overrides` structures, one with `InstanceRequirements` and the other with `InstanceType`
- Two `InstanceRequirements` structures with overlapping attribute values within the same `LaunchTemplateSpecification`

Example configurations

- [Valid configuration: Single launch template with overrides \(p. 807\)](#)
- [Valid configuration: Single launch template with multiple InstanceRequirements \(p. 808\)](#)
- [Valid configuration: Two launch templates, each with overrides \(p. 809\)](#)
- [Configuration not valid: Overrides contain InstanceRequirements and InstanceType \(p. 810\)](#)
- [Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType \(p. 810\)](#)
- [Valid configuration: Only InstanceRequirements specified, no overlapping attribute values \(p. 811\)](#)
- [Configuration not valid: Overlapping attribute values \(p. 812\)](#)

Valid configuration: Single launch template with overrides

The following configuration is valid. It contains one launch template and one `Overrides` structure containing one `InstanceRequirements` structure. A text explanation of the example configuration follows.

```
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "My-launch-template",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 2,
                            "Max": 8
                        },
                        "MemoryMib": {
                            "Min": 0,
                            "Max": 10240
                        },
                        "MemoryGiBPerVCpu": {

                        "RequireHibernateSupport": true
                    }
                }
            ]
        }
    ]
}
```

```
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 5000,
        "DefaultTargetCapacityType": "spot",
        "TargetCapacityUnitType": "vcpu"
    }
}
```

InstanceRequirements

To use attribute-based instance selection, you must include the `InstanceRequirements` structure in your fleet configuration, and specify the desired attributes for the instances in the fleet.

In the preceding example, the following instance attributes are specified:

- `VCpuCount` – The instance types must have a minimum of 2 and a maximum of 8 vCPUs.
- `MemoryMiB` – The instance types must have a maximum of 10240 MiB of memory. A minimum of 0 indicates no minimum limit.
- `MemoryGiBPerVCpu` – The instance types must have a maximum of 10,000 GiB of memory per vCPU. The `Min` parameter is optional. By omitting it, you indicate no minimum limit.

TargetCapacityUnitType

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5,000 vCPUs. EC2 Fleet will launch enough instances so that the total number of vCPUs in the fleet is 5,000 vCPUs.

Valid configuration: Single launch template with multiple InstanceRequirements

The following configuration is valid. It contains one launch template and one `Overrides` structure containing two `InstanceRequirements` structures. The attributes specified in `InstanceRequirements` are valid because the values do not overlap—the first `InstanceRequirements` structure specifies a `VCpuCount` of 0-2 vCPUs, while the second `InstanceRequirements` structure specifies 4-8 vCPUs.

```

                "LaunchTemplateName": "MyLaunchTemplate",
                "Version": "1"
            },
            "Overrides": [

Valid configuration: Two launch templates, each with overrides

The following configuration is valid. It contains two launch templates, each with one `Overrides` structure containing one `InstanceRequirements` structure. This configuration is useful for `arm` and `x86` architecture support in the same fleet.

```
{  
    "LaunchTemplateConfigs": [  
        {  
            "LaunchTemplateSpecification": {

Configuration not valid: Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The `Overrides` structure contains both `InstanceRequirements` and `InstanceType`. For the `Overrides`, you can specify either `InstanceRequirements` or `InstanceType`, but not both.

```

Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The `Overrides` structures contain both `InstanceRequirements` and `InstanceType`. You can specify either `InstanceRequirements` or `InstanceType`, but not both, even if they're in different `Overrides` structures.

```
{
    "LaunchTemplateConfigs": [

Valid configuration: Only InstanceRequirements specified, no overlapping attribute values

The following configuration is valid. It contains two LaunchTemplateSpecification structures, each with a launch template and an Overrides structure containing an InstanceRequirements structure. The attributes specified in InstanceRequirements are valid because the values do not overlap—the first InstanceRequirements structure specifies a VCpuCount of 0-2 vCPUs, while the second InstanceRequirements structure specifies 4-8 vCPUs.

```
{
    "LaunchTemplateConfigs": [

Configuration not valid: Overlapping attribute values

The following configuration is not valid. The two `InstanceRequirements` structures each contain `"VCpuCount": {"Min": 0, "Max": 2}`. The values for these attributes overlap, which will result in duplicate capacity pools.

```
{
    "LaunchTemplateConfigs": [

Preview instance types with specified attributes

You can use the [get-instance-types-from-instance-requirements](#) AWS CLI command to preview the instance types that match the attributes that you specify. This is especially useful for working out what attributes to specify in your request configuration without launching any instances. Note that the command does not consider available capacity.

To preview a list of instance types by specifying attributes using the AWS CLI

1. (Optional) To generate all of the possible attributes that can be specified, use the `get-instance-types-from-instance-requirements` command and the `--generate-cli-skeleton` parameter. You can optionally direct the output to a file to save it by using `input > attributes.json`.

```
aws ec2 get-instance-types-from-instance-requirements \
--region us-east-1 \
--generate-cli-skeleton input > attributes.json
```

Expected output

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

Note

You must provide values for `ArchitectureTypes`, `VirtualizationTypes`, `VCpuCount`, and `MemoryMiB`. You can omit the other attributes; when omitted, the default values are used.

For a description of each attribute and their default values, see [get-instance-types-from-instance-requirements](#) in the *Amazon EC2 Command Line Reference*.

- a. For `ArchitectureTypes`, specify one or more types of processor architecture.
 - b. For `VirtualizationTypes`, specify one or more types of virtualization.
 - c. For `VCpuCount`, specify the minimum and maximum number of vCPUs. To specify no minimum limit, for `Min`, specify 0. To specify no maximum limit, omit the `Max` parameter.
 - d. For `MemoryMiB`, specify the minimum and maximum amount of memory in MiB. To specify no minimum limit, for `Min`, specify 0. To specify no maximum limit, omit the `Max` parameter.
 - e. You can optionally specify one or more of the other attributes to further constrain the list of instance types that are returned.
3. To preview the instance types that have the attributes that you specified in the JSON file, use the `get-instance-types-from-instance-requirements` command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter. You can optionally format the output to appear in a table format.

```
aws ec2 get-instance-types-from-instance-requirements \
--cli-input-json file://attributes.json \
--output table
```

Example `attributes.json` file

In this example, the required attributes are included in the JSON file. They are `ArchitectureTypes`, `VirtualizationTypes`, `VCpuCount`, and `MemoryMiB`. In addition, the optional `InstanceGenerations` attribute is also included. Note that for `MemoryMiB`, the `Max` value can be omitted to indicate that there is no limit.

```
{  
    "ArchitectureTypes": [  
        "x86_64"  
    ],  
    "VirtualizationTypes": [  
        "hvm"  
    ],  
    "InstanceRequirements": {  
        "VCpuCount": {  
            "Min": 4,  
            "Max": 6  
        },  
        "MemoryMiB": {  
            "Min": 2048  
        },  
        "InstanceGenerations": [  
            "current"  
        ]  
    }  
}
```

Example output

```
|GetInstanceTypesFromInstanceRequirements|

4. After identifying instance types that meet your needs, make note of the instance attributes that you used so that you can use them when configuring your fleet request.

Configure EC2 Fleet for On-Demand backup

If you have urgent, unpredictable scaling needs, such as a news website that must scale during a major news event or game launch, we recommend that you specify alternative instance types for your On-Demand Instances, in the event that your preferred option does not have sufficient available capacity. For example, you might prefer `c5.2xlarge` On-Demand Instances, but if there is insufficient available capacity, you'd be willing to use some `c4.2xlarge` instances during peak load. In this case, EC2 Fleet attempts to fulfill all of your target capacity using `c5.2xlarge` instances, but if there is insufficient capacity, it automatically launches `c4.2xlarge` instances to fulfill the target capacity.

Prioritize instance types for On-Demand capacity

When EC2 Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest-priced instance type first. If `AllocationStrategy` is set to `prioritized`, EC2 Fleet uses priority to determine which instance type to use first in fulfilling On-Demand capacity. The priority is assigned to the launch template override, and the highest priority is launched first.

For example, you have configured three launch template overrides, each with a different instance type: `c3.large`, `c4.large`, and `c5.large`. The On-Demand price for `c5.large` is less than the price for `c4.large`. `c3.large` is the cheapest. If you do not use priority to determine the order, the fleet fulfills On-Demand capacity by starting with `c3.large`, and then `c5.large`. Because you often have unused Reserved Instances for `c4.large`, you can set the launch template override priority so that the order is `c4.large`, `c3.large`, and then `c5.large`.

Use Capacity Reservations for On-Demand Instances

With On-Demand Capacity Reservations, you can reserve compute capacity for your On-Demand Instances in a specified Availability Zone for any duration. You can configure an EC2 Fleet to use the Capacity Reservations first when launching On-Demand Instances.

Capacity Reservations are configured as either open or targeted. EC2 Fleet can launch On-Demand Instances into either open or targeted Capacity Reservations, as follows:

- If a Capacity Reservation is open, On-Demand Instances that have matching attributes automatically run in the reserved capacity.
- If a Capacity Reservation is targeted, On-Demand Instances must specifically target it to run in the reserved capacity. This is useful for using up specific Capacity Reservations or for controlling when to use specific Capacity Reservations.

If you use targeted Capacity Reservations in your EC2 Fleet, there must be enough Capacity Reservations to fulfil the target On-Demand capacity, otherwise the launch fails. To avoid a launch fail, rather add the targeted Capacity Reservations to a resource group, and then target the resource group. The resource group doesn't need to have enough Capacity Reservations; if it runs out of Capacity Reservations before the target On-Demand capacity is fulfilled, the fleet can launch the remaining target capacity into regular On-Demand capacity.

To use Capacity Reservations with EC2 Fleet

1. Configure the fleet as type `instant`. You can't use Capacity Reservations for fleets of other types.
2. Configure the usage strategy for Capacity Reservations as `use-capacity-reservations-first`.
3. In the launch template, for **Capacity reservation**, choose either **Open** or **Target by group**. If you choose **Target by group**, specify the Capacity Reservations resource group ID.

When the fleet attempts to fulfil the On-Demand capacity, if it finds that multiple instance pools have unused matching Capacity Reservations, it determines the pools in which to launch the On-Demand Instances based on the On-Demand allocation strategy (`lowest-price` or `prioritized`).

For examples of how to configure a fleet to use Capacity Reservations to fulfil On-Demand capacity, see [EC2 Fleet example configurations \(p. 917\)](#), specifically Examples 5 through 7.

For information about configuring Capacity Reservations, see [On-Demand Capacity Reservations \(p. 538\)](#) and the [On-Demand Capacity Reservation FAQs](#).

Capacity Rebalancing

You can configure EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation to notify you that a Spot Instance is at an elevated risk of interruption. Capacity

Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance is interrupted by Amazon EC2. For more information, see [EC2 instance rebalance recommendations \(p. 472\)](#).

To configure EC2 Fleet to launch a replacement Spot Instance, use the [create-fleet](#) (AWS CLI) command and the relevant parameters in the `MaintenanceStrategies` structure. For more information, see the [example launch configuration \(p. 927\)](#).

Limitations

- Capacity Rebalancing is available only for fleets of type `maintain`.
- When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

Configuration options

The `ReplacementStrategy` for EC2 Fleet supports the following two values:

`launch-before-terminate`

EC2 Fleet terminates the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched. When you specify `launch-before-terminate`, you must also specify a value for `termination-delay`. After the new replacement instances are launched, EC2 Fleet waits for the duration of the `termination-delay`, and then terminates the old instances. For `termination-delay`, the minimum is 120 seconds (2 minutes), and the maximum is 7200 seconds (2 hours).

We recommend that you use `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed. Note that Amazon EC2 can interrupt the old instances with a two-minute warning before the `termination-delay`.

We strongly recommend against using the lowest-price allocation strategy in combination with `launch-before-terminate` to avoid having replacement Spot Instances that are also at an elevated risk of interruption.

`launch`

EC2 Fleet launches replacement Spot Instances when a rebalance notification is emitted for existing Spot Instances. EC2 Fleet does not terminate the instances that receive a rebalance notification. You can terminate the old instances, or you can leave them running. You are charged for all instances while they are running.

Considerations

If you configure an EC2 Fleet for Capacity Rebalancing, consider the following:

EC2 Fleet can launch new replacement Spot Instances until fulfilled capacity is double target capacity

When an EC2 Fleet is configured for Capacity Rebalancing, the fleet attempts to launch a new replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled capacity. Depending on the replacement strategy, EC2 Fleet either terminates the instance after a preconfigured termination delay, or leaves it running. This gives you the opportunity to perform [rebalancing actions \(p. 472\)](#) on the instance.

If your fleet reaches double its target capacity, it stops launching new replacement instances even if the replacement instances themselves receive a rebalance recommendation.

For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. All of the Spot Instances receive a rebalance recommendation, which causes EC2 Fleet to launch 100 replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is double the target capacity. Some of the replacement instances receive a rebalance recommendation, but no more replacement instances are launched because the fleet cannot exceed double its target capacity.

Note that you are charged for all of the instances while they are running.

We recommend that you configure EC2 Fleet to terminate Spot Instances that receive a rebalance recommendation

If you configure your EC2 Fleet for Capacity Rebasing, we recommend that you choose `launch-before-terminate` with an appropriate termination delay only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed.

If you choose to terminate the instances that are recommended for rebalance yourself, we recommend that you monitor the rebalance recommendation signal that is received by the Spot Instances in the fleet. By monitoring the signal, you can quickly perform [rebalancing actions \(p. 472\)](#) on the affected instances before Amazon EC2 interrupts them, and then you can manually terminate them. If you do not terminate the instances, you continue paying for them while they are running. EC2 Fleet does not automatically terminate the instances that receive a rebalance recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information, see [Monitor rebalance recommendation signals \(p. 473\)](#).

EC2 Fleet does not count instances that receive a rebalance recommendation when calculating fulfilled capacity during scale in or out

If your EC2 Fleet is configured for Capacity Rebasing, and you change the target capacity to either scale in or scale out, the fleet does not count the instances that are marked for rebalance as part of the fulfilled capacity, as follows:

- Scale in – If you decrease your desired target capacity, the fleet terminates instances that are not marked for rebalance until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for rebalance are not terminated by the fleet. You need to manually terminate these instances, or you can leave them running.

- Scale out – If you increase your desired target capacity, the fleet launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

Provide as many Spot capacity pools in the request as possible

Configure your EC2 Fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see [Be flexible about instance types and Availability Zones \(p. 443\)](#).

Avoid an elevated risk of interruption of replacement Spot Instances

Your replacement Spot Instances may be at an elevated risk of interruption if you use the lowest-price allocation strategy. This is because Amazon EC2 will always launch instances in the lowest-priced pool that has available capacity at that moment, even if your replacement Spot Instances are likely to be interrupted soon after being launched. To avoid an elevated risk of interruption, we strongly recommend against using the lowest-price allocation strategy, and instead recommend the capacity-optimized or capacity-optimized-prioritized allocation strategy. These strategies ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools, and are therefore less likely to be interrupted in the near future. For more information, see [Use the capacity optimized allocation strategy \(p. 443\)](#).

Maximum price overrides

Each EC2 Fleet can either include a global maximum price, or use the default (the On-Demand price). The fleet uses this as the default maximum price for each of its launch specifications.

You can optionally specify a maximum price in one or more launch specifications. This price is specific to the launch specification. If a launch specification includes a specific price, the EC2 Fleet uses this maximum price, overriding the global maximum price. Any other launch specifications that do not include a specific maximum price still use the global maximum price.

Control spending

EC2 Fleet stops launching instances when it has met one of the following parameters: the `TotalTargetCapacity` or the `MaxTotalPrice` (the maximum amount you're willing to pay). To control the amount you pay per hour for your fleet, you can specify the `MaxTotalPrice`. When the maximum total price is reached, EC2 Fleet stops launching instances even if it hasn't met the target capacity.

The following examples show two different scenarios. In the first, EC2 Fleet stops launching instances when it has met the target capacity. In the second, EC2 Fleet stops launching instances when it has reached the maximum amount you're willing to pay (`MaxTotalPrice`).

Example: Stop launching instances when target capacity is reached

Given a request for `m4.large` On-Demand Instances, where:

- On-Demand Price: \$0.10 per hour
- `OnDemandTargetCapacity`: 10
- `MaxTotalPrice`: \$1.50

EC2 Fleet launches 10 On-Demand Instances because the total of \$1.00 (10 instances x \$0.10) does not exceed the `MaxTotalPrice` of \$1.50 for On-Demand Instances.

Example: Stop launching instances when maximum total price is reached

Given a request for `m4.large` On-Demand Instances, where:

- On-Demand Price: \$0.10 per hour
- `OnDemandTargetCapacity`: 10
- `MaxTotalPrice`: \$0.80

If EC2 Fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be \$1.00. This is more than the amount (\$0.80) specified for `MaxTotalPrice` for On-Demand Instances. To prevent spending more than you're willing to pay, EC2 Fleet launches only 8 On-

Demand Instances (below the On-Demand target capacity) because launching more would exceed the `MaxTotalPrice` for On-Demand Instances.

EC2 Fleet instance weighting

When you create an EC2 Fleet, you can define the capacity units that each instance type would contribute to your application's performance. You can then adjust your maximum price for each launch specification by using *instance weighting*.

By default, the price that you specify is *per instance hour*. When you use the instance weighting feature, the price that you specify is *per unit hour*. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. EC2 Fleet calculates the number of instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer, the fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. The fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following table includes examples of calculations to determine the price per unit for an EC2 Fleet with a target capacity of 10.

Instance type	Instance weight	Target capacity	Number of instances launched	Price per instance hour	Price per unit hour
r3.xlarge	2	10	5 (10 divided by 2)	\$0.05	\$0.025 (.05 divided by 2)
r3.8xlarge	8	10	2 (10 divided by 8, result rounded up)	\$0.10	\$0.0125 (.10 divided by 8)

Use EC2 Fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your EC2 Fleet either in instances (the default) or in the units of your choice, such as virtual CPUs, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch specification, specify the weight, which is the number of units that the instance type represents toward the target capacity.

Instance weighting example

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 24
- A launch specification with an instance type r3.2xlarge and a weight of 6
- A launch specification with an instance type c3.xlarge and a weight of 5

The weights represent the number of units that instance type represents toward the target capacity. If the first launch specification provides the lowest price per unit (price for r3.2xlarge per instance hour divided by 6), the EC2 Fleet would launch four of these instances (24 divided by 6).

If the second launch specification provides the lowest price per unit (price for `c3.xlarge` per instance hour divided by 5), the EC2 Fleet would launch five of these instances (24 divided by 5, result rounded up).

Instance weighting and allocation strategy

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 30 Spot Instances
- A launch specification with an instance type `c3.2xlarge` and a weight of 8
- A launch specification with an instance type `m3.xlarge` and a weight of 8
- A launch specification with an instance type `r3.xlarge` and a weight of 8

The EC2 Fleet would launch four instances (30 divided by 8, result rounded up). With the `lowest-price` strategy, all four instances come from the pool that provides the lowest price per unit. With the `diversified` strategy, the fleet launches one instance in each of the three pools, and the fourth instance in whichever of the three pools provides the lowest price per unit.

Work with EC2 Fleets

To start using an EC2 Fleet, you create a request that includes the total target capacity, On-Demand capacity, Spot capacity, one or more launch specifications for the instances, and the maximum price that you are willing to pay. The fleet request must include a launch template that defines the information that the fleet needs to launch an instance, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups. You can specify launch specification overrides for the instance type, subnet, Availability Zone, and maximum price you're willing to pay, and you can assign weighted capacity to each launch specification override.

The EC2 Fleet launches On-Demand Instances when there is available capacity, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

If your fleet includes Spot Instances, Amazon EC2 can attempt to maintain your fleet target capacity as Spot prices change.

An EC2 Fleet request of type `maintain` or `request` remains active until it expires or you delete it. When you delete a fleet of type `maintain` or `request`, you can specify whether deletion terminates the instances in that fleet. Otherwise, the On-Demand Instances run until you terminate them, and the Spot Instances run until they are interrupted or you terminate them.

EC2 Fleet request states

An EC2 Fleet request can be in one of the following states:

submitted

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. The request can include On-Demand Instances, Spot Instances, or both.

active

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances. The request remains in this state until it is modified or deleted.

modifying

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed or the request is deleted. Only a `maintain` fleet type can be modified. This state does not apply to other request types.

deleted_running

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated manually. The request remains in this state until all instances are interrupted or terminated. Only an EC2 Fleet of type `maintain` or `request` can have running instances after the EC2 Fleet request is deleted. A deleted instant fleet with running instances is not supported. This state does not apply to instant fleets.

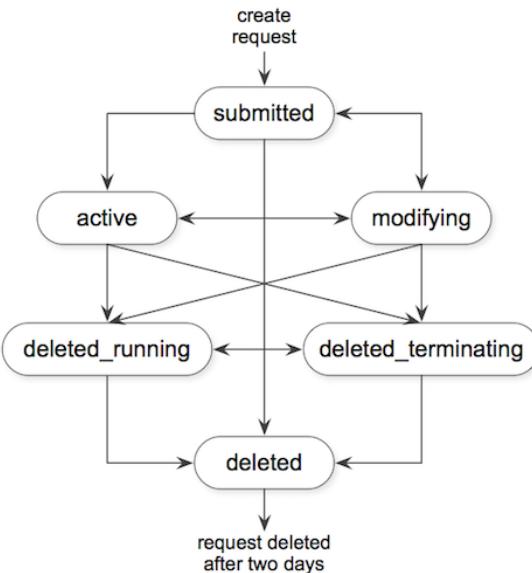

deleted_terminating

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

deleted

The EC2 Fleet is deleted and has no running instances. The request is deleted two days after its instances are terminated.

The following illustration represents the transitions between the EC2 Fleet request states. If you exceed your fleet limits, the request is deleted immediately.

EC2 Fleet prerequisites

To create an EC2 Fleet, the following prerequisites must be in place:

- [Launch template \(p. 823\)](#)

- [Service-linked role for EC2 Fleet \(p. 823\)](#)
- [Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots \(p. 823\)](#)
- [Permissions for EC2 Fleet IAM users \(p. 824\)](#)

Launch template

A launch template includes information about the instances to launch, such as the instance type, Availability Zone, and the maximum price that you are willing to pay. For more information, see [Launch an instance from a launch template \(p. 594\)](#).

Service-linked role for EC2 Fleet

The `AWSServiceRoleForEC2Fleet` role grants the EC2 Fleet permission to request, launch, terminate, and tag instances on your behalf. Amazon EC2 uses this service-linked role to complete the following actions:

- `ec2:RunInstances` – Launch instances.
- `ec2:RequestSpotInstances` – Request Spot Instances.
- `ec2:TerminateInstances` – Terminate instances.
- `ec2:DescribeImages` – Describe Amazon Machine Images (AMIs) for the Spot Instances.
- `ec2:DescribeInstanceStatus` – Describe the status of the Spot Instances.
- `ec2:DescribeSubnets` – Describe the subnets for Spot Instances.
- `ec2:CreateTags` – Add tags to the EC2 Fleet, instances, and volumes.

Ensure that this role exists before you use the AWS CLI or an API to create an EC2 Fleet.

Note

An instant EC2 Fleet does not require this role.

To create the role, use the IAM console as follows.

To create the `AWSServiceRoleForEC2Fleet` role for EC2 Fleet

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select type of trusted entity**, choose **AWS service**.
4. For **Choose the service that will use this role**, choose **EC2 - Fleet**, and then choose **Next: Permissions**, **Next: Tags**, and **Next: Review**.
5. On the **Review** page, choose **Create role**.

If you no longer need to use EC2 Fleet, we recommend that you delete the `AWSServiceRoleForEC2Fleet` role. After this role is deleted from your account, you can create the role again if you create another fleet.

For more information, see [Using service-linked roles in the IAM User Guide](#).

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an [encrypted AMI \(p. 203\)](#) or an [encrypted Amazon EBS snapshot \(p. 1542\)](#) in your EC2 Fleet and you use an AWS KMS key for encryption, you must grant the `AWSServiceRoleForEC2Fleet` role permission to use the customer managed key so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using grants](#) and [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

To grant the **AWSServiceRoleForEC2Fleet** role permissions to use the customer managed key

- Use the [create-grant](#) command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Fleet** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the `key-id` parameter and the ARN of the customer managed key. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2Fleet** service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-
east-1:44445556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Fleet \
    --operations "Decrypt" "Encrypt" "GenerateDataKey"
"GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
"ReEncryptTo"
```

Permissions for EC2 Fleet IAM users

If your IAM users will create or manage an EC2 Fleet, be sure to grant them the required permissions as follows.

To grant an IAM user permissions for EC2 Fleet

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create policy** page, choose the **JSON** tab, replace the text with the following, and choose **Review policy**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam>ListRoles",
                "iam>PassRole",
                "iam>ListInstanceProfiles"
            ],
            "Resource": "arn:aws:iam::123456789012:role/DevTeam*"
        }
    ]
}
```

The `ec2:*` grants an IAM user permission to call all Amazon EC2 API actions. To limit the user to specific Amazon EC2 API actions, specify those actions instead.

An IAM user must have permission to call the `iam>ListRoles` action to enumerate existing IAM roles, the `iam>PassRole` action to specify the EC2 Fleet role, and the `iam>ListInstanceProfiles` action to enumerate existing instance profiles.

(Optional) To enable an IAM user to create roles or instance profiles using the IAM console, you must also add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
 - `iam:AttachRolePolicy`
 - `iam>CreateInstanceProfile`
 - `iam:CreateRole`
 - `iam:GetRole`
 - `iam>ListPolicies`
5. On the **Review policy** page, enter a policy name and description, and choose **Create policy**.
 6. In the navigation pane, choose **Users** and select the user.
 7. On the **Permissions** tab, choose **Add permissions**.
 8. Choose **Attach existing policies directly**. Select the policy that you created earlier and choose **Next: Review**.
 9. Choose **Add permissions**.

EC2 Fleet health checks

EC2 Fleet checks the health status of the instances in the fleet every two minutes. The health status of an instance is either healthy or unhealthy.

EC2 Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as unhealthy when the status of either the instance status check or the system status check is impaired for three consecutive health status checks. For more information, see [Status checks for your instances \(p. 945\)](#).

You can configure your fleet to replace unhealthy Spot Instances. After setting `ReplaceUnhealthyInstances` to `true`, a Spot Instance is replaced when it is reported as unhealthy. The fleet can go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

- Health check replacement is supported only for EC2 Fleets that maintain a target capacity (fleets of type `maintain`), and not for fleets of type `request` or `instant`.
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your EC2 Fleet to replace unhealthy instances only when you create it.
- IAM users can use health check replacement only if they have permission to call the `ec2:DescribeInstanceStatus` action.

To configure an EC2 Fleet to replace unhealthy Spot Instances

1. Follow the steps for creating an EC2 Fleet. For more information, see [Create an EC2 Fleet \(p. 828\)](#).
2. To configure the fleet to replace unhealthy Spot Instances, in the JSON file, for `ReplaceUnhealthyInstances`, enter `true`.

Generate an EC2 Fleet JSON configuration file

To view the full list of EC2 Fleet configuration parameters, you can generate a JSON file. For a description of each parameter, see [create-fleet](#) in the AWS CLI Command Reference.

To generate a JSON file with all possible EC2 Fleet parameters using the command line

- Use the [create-fleet](#) (AWS CLI) command and the --generate-cli-skeleton parameter to generate an EC2 Fleet JSON file, and direct the output to a file to save it.

```
aws ec2 create-fleet \
--generate-cli-skeleton input > ec2createfleet.json
```

Create an EC2 Fleet

To create an EC2 Fleet, you need only specify the following parameters:

- **LaunchTemplateId** or **LaunchTemplateName** – Specifies the launch template to use (which contains the parameters for the instances to launch, such as the instance type, Availability Zone, and the maximum price you're willing to pay)
- **TotalTargetCapacity** – Specifies the total target capacity for the fleet
- **DefaultTargetCapacityType** – Specifies whether the default purchasing option is On-Demand or Spot

You can specify multiple launch specifications that override the launch template. The launch specifications can vary by instance type, Availability Zone, subnet, and maximum price, and can include a different weighted capacity. Alternatively, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. For more information, see [Attribute-based instance type selection for EC2 Fleet \(p. 801\)](#).

If you do not specify a parameter, the fleet uses the default value for the parameter.

Specify the fleet parameters in a JSON file. For more information, see [Generate an EC2 Fleet JSON configuration file \(p. 825\)](#).

EC2 Fleets can only be created using the AWS CLI.

To create an EC2 Fleet (AWS CLI)

- Use the `create-fleet` (AWS CLI) command to create an EC2 Fleet and specify the JSON file that contains the fleet configuration parameters.

```
aws ec2 create-fleet --cli-input-json file://file_name.json
```

For example configuration files, see [EC2 Fleet example configurations \(p. 917\)](#).

Tag an EC2 Fleet

To help categorize and manage your EC2 Fleet requests, you can tag them with custom metadata. You can assign a tag to an EC2 Fleet request when you create it, or afterward.

When you tag a fleet request, the instances and volumes that are launched by the fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the fleet. You can choose to assign tags to only the fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all three.

Note

For instant fleet types, you can tag volumes that are attached to On-Demand Instances and Spot Instances. For request or maintain fleet types, you can only tag volumes that are attached to On-Demand Instances.

For more information about how tags work, see [Tag your Amazon EC2 resources \(p. 1692\)](#).

Prerequisite

Grant the IAM user the permission to tag resources. For more information, see [Example: Tag resources \(p. 1280\)](#).

To grant an IAM user the permission to tag resources

Create a IAM policy that includes the following:

- The `ec2:CreateTags` action. This grants the IAM user permission to create tags.
- The `ec2:CreateFleet` action. This grants the IAM user permission to create an EC2 Fleet request.
- For `Resource`, we recommend that you specify `"*"`. This allows users to tag all resource types.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "TagEC2FleetRequest",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags",
                "ec2:CreateFleet"
            ],
            "Resource": "*"
    }
}
```

Important

We currently do not support resource-level permissions for the `create-fleet` resource. If you specify `create-fleet` as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how *not* to set the policy.

```
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateTags",
        "ec2:CreateFleet"
    ],
    "Resource": "arn:aws:ec2:us-east-1:11122223333:create-fleet/*"
}
```

To tag a new EC2 Fleet request

To tag an EC2 Fleet request when you create it, specify the key-value pair in the [JSON file \(p. 825\)](#) used to create the fleet. The value for `ResourceType` must be `fleet`. If you specify another value, the fleet request fails.

To tag instances and volumes launched by an EC2 Fleet

To tag instances and volumes when they are launched by the fleet, specify the tags in the [launch template \(p. 596\)](#) that is referenced in the EC2 Fleet request.

Note

You can't tag volumes attached to Spot Instances that are launched by a `request` or `maintain` fleet type.

To tag an existing EC2 Fleet request, instance, and volume (AWS CLI)

Use the [create-tags](#) command to tag existing resources.

```
aws ec2 create-tags \
  --resources fleet-12a34b55-67cd-8ef9-
  ba9b-9208dEXAMPLE i-1234567890abcdef0 vol-1234567890EXAMPLE \
  --tags Key=purpose,Value=test
```

Describe your EC2 Fleet

You can describe your EC2 Fleet configuration, the instances in your EC2 Fleet, and the event history of your EC2 Fleet.

To describe your EC2 Fleets (AWS CLI)

Use the [describe-fleets](#) command to describe your EC2 Fleets.

```
aws ec2 describe-fleets
```

Important

If a fleet is of type `instant`, you must specify the fleet ID, otherwise it does not appear in the response. Include `--fleet-ids` as follows:

```
aws ec2 describe-fleets --fleet-ids fleet-8a22eeee4-f489-ab02-06b8-832a7EXAMPLE
```

Example output

```
